FROM VITAL \& HEALTH STATISTICS OF THE NATIONAL CENTER FOR HE,
U.S. DEPARTMENT OF HEALTH, EDUCATION, AND WELFARE $\mid$ No. 2 November 8, $1976 \mid$ Public Health Service - He:

## HYPERTENSION: UNITED STATES, $1974{ }^{\text {a }}$

During 1974 the Division of Health Interview Statistics obtained hypertension prevalence estimates for the U.S. civilian noninstitutionalized population 17 years of age and over. While hypertension data have been collected by this Division in the past, this was the first year for earmarking this condition as a supplemental topic, enabling the collection of more detailed information than had been obtained previously.

Special interest in this disease was generated in 1972 with the establishment of the National High Blood Pressure Education Program. The long-range goal of this program is to lower the morbidity and mortality associated with high blood pressure existing in this country today through improved detection and treatment of this disease. A more immediate program objective, however, is the education of both the public and the medical community about high blood pressure.

This report contains population estimates for four hypertension status categories, "ever

[^0]had hypertension," "now have hypertension," "no longer have hypertension," and "never had hypertension," by seven demographic character-istics-age, sex, race, family income, education of individual, and geographic region and place of residence. Data on a limited number of supplemental items are also included. A more detailed report containing further analysis of these and other related data is being prepared.

The following criteria were used to classify persons into four hypertension status categories which were developed for the purpose of presenting the hypertension data obtained by the Division of Health Interview Statistics.

Persons comprising the category "ever had hypertension" reported that they were told by a medical doctor that they had either hypertension or high blood pressure. These persons are also classified according to their current hypertension status: (1) persons who "now have hypertension" reported that they still had hypertension (high blood pressure) at the time of the interview, that it was under control, or that they were taking medicine prescribed by a doctor for it; (2) persons who "no longer have hypertension" reported that this condition was cured and

$$

that they were not presently taking medicine prescribed by a doctor for it. Note that to be classified to either category "now have hypertension" or "no longer have hypertension" a person also had to have been told at some time by a medical doctor that he had high blood pressure or hypertension. The category "never had hypertension" comprises persons who were never told by a medical doctor that they had hypertension or high blood pressure.

According to data obtained in 1974 by the Division of Health Interview Statistics, one in five persons comprising the civilian noninstitutionalized population of the United States 17 years of age and over ( 20.6 percent) has been told by a doctor that he has hypertension, and an estimated 22.6 million Americans at these ages ( 15.7 percent) still have this condition (table 1). There are marked differences in the percents of persons that now have hypertension for specific sex, age, and race groups.

Proportionately more women ( 18.5 percent) than men ( 12.5 percent) currently have hypertension. This sex difference was apparent among every age group shown in table 1 except those
aged 17-24 years, where the percents of young hypertensive men and women were about the same. The likelihood of having this condition also increased with advancing age. Whereas about 4 percent of all persons aged $17-24$ years now have hypertension, this proportion rose to 35 percent of all persons 65 years of age and over.

Proportionately more black persons (22.2 percent) than white ( 15.0 percent) currently have hypertension. This pattern was evident for each age group except those aged 17-24 years; differences between white persons and black of these ages were within sampling variation. Among all persons 17 years of age and over, white males had the lowest proportion (12.0 percent) of hypertensives, and black females had the highest proportion ( 25.9 percent) of hypertensives, as shown in the chart, while similar proportions with hypertension were found for white females ( 17.7 percent) and black males ( 17.4 percent). Percent differences between white females and black males with hypertension for the age groups $25-44,45-64$, and 65 years and over may be due to sampling variability.

When hypertension data are displayed by family income, education of the individual, and geographic region and place of residence the following patterns are found. As family income rose, the percent of persons with hypertension declined-from 25.7 percent of those with incomes of less than $\$ 5,000$ to 11.8 percent when income reached $\$ 10,000$ or more (table 2). A disproportionate number of older persons and black persons in the lower income bracket, however, account for some of this difference. For example, when these data were age-adjusted to the age distribution of the United States population 17 years and over (see Technical Notes), the percent changed as follows:

|  | Percent |  |
| :--- | :---: | :---: |
|  | Unadjusted | Age-adjusted |
| Less than $\$ 5,000 \ldots$ | 25.7 | 22.0 |
| $\$ 5,000-\$ 9,999 \ldots$ | 17.2 | 17.1 |
| $\$ 10,000$ or more $\ldots$ | 11.8 | 13.3 |

Likewise, as level of education increased the percent of persons with hypertension decreased. An estimated 22 percent of all persons who were not high school graduates now have hypertension compared with about 13 percent of high school graduates and about 10 percent of persons completing 1 year or more of college.

The South had the highest proportion of persons with hypertension ( 16.9 percent) of any geographic region in the country. A slightly greater percent of persons residing outside of standard metropolitan statistical areas (SMSA's) ( 16.9 percent) currently had hypertension than did those living within SMSA's ( 15.1 percent). Within SMSA's, the proportion of hypertensives was more than 20 percent higher among people living in the central city ( 16.8 percent) than those living in adjacent areas ( 13.8 percent).

Most health practitioners agree that all persons should have a blood pressure test periodically. Based on 1974 Health Interview Survey findings, almost two-thirds of all persons aged 17 years and over were given a test of this kind within the 12 -month period preceding the interview (table 3).

The percent of persons with a 12 -month blood pressure test gradually increased with each older age group, from 62.6 percent of those $17-44$ years to 70.4 percent of persons 65 years
and over. Proportionately more females (71.8 percent) than males ( 56.5 percent) had a test within the year, while about the same proportion of white persons and black were given a blood pressure test during this period. An estimated 1.4 million people 17 years of age or older (about 1 percent of the U.S. civilian noninstitutionalized adult population) reported they had never had a blood pressure test.

The percents of persons having a blood pressure test during the previous year were somewhat higher for the currently hypertensive population than for the general population. About 86 percent of the currently hypertensive population had their blood pressure taken within 12 months of the date of interview, and three out of every four persons with high blood pressure had a test as recently as within 6 months of the interview.

Proportionately more females than males now with hypertension had a blood pressure test within the past 6 months ( 76.3 compared with 70.4 percent) and within the past 12 months ( 87.8 compared with 83.5 percent). The proportion of currently hypertensive persons with a blood pressure test during the 6 -month period also rose with each older age group, from 66.9 percent of those aged $17-44$ years to 78.6 percent of those aged 65 years and over. However for the 12 -month period preceding the interview, although proportionately more persons 45 years and over had a blood pressure test than did younger persons, the percents with a test during this period for the two age groups 45-64 and 65 years and over were about the same.

Of persons with a blood pressure test within the year, the proportion having multiple tests during this period rose as age increased-from 58.2 percent of persons $17-44$ years to 73.6 percent of those 65 years or older. The percent with two tests or more was higher for females ( 65.7 percent) than it was for males ( 56.9 percent), and it was higher for black persons ( 67.3 percent) than it was for white persons ( 61.5 percent). Proportionately more persons now having hypertension had multiple blood pressure tests during the year than did the total U.S. civilian noninstitutionalized population (81.4 percent compared with 62.1 percient).

Persons whose blood pressure was taken in the past year are classified according to the last test result (table 4). Of the total United States
civilian noninstitutionalized population 17 years of age and over with blood pressure taken in the past year, a little more than half ( 53.1 percent) were told their last blood pressure reading was normal. Males had a higher percent of normal readings than did females ( 57.3 percent compared with 50.2 percent). About the same percent of males and females had a blood pressure reading that was high ( 7.1 and 7.8 percent, respectively), while females had almost twice as high a percentile of blood pressure results that were low as did males ( 4.8 compared with 2.6 percent).

By race, proportionately more black persons (10.7 percent) than white ( 7.1 percent) 17 years and over had a blood pressure reading that was high.

About the same proportion of white persons ( 4.0 percent) and black ( 3.2 percent) had a blood pressure reading that was low. Overall, the proportion of persons having a blood pressure reading that was high was much greater among persons now having hypertension ( 29.7 percent) than among the total United States adult population ( 7.5 percent).

Data on doctor visits and bed days for hypertension which occurred during the 12 -month period preceding the interview are presented in table 5. About three-fourths of the currently hypertensive population saw a doctor for this condition at least once during the year, while 26.9 percent reported five doctor visits or more. The percent of currently hypertensive persons with one doctor visit or more of this kind increased somewhat for two broad age groupsfrom about 62 percent of persons aged 17-44 years to about 77 percent of all persons aged 45 years and over. Over one-third of all persons comprising the oldest age category had five doctor visits or more for hypertension within this period compared with only about 9 percent of persons 17-24 years of age.

The percent of persons reporting one doctor visit or more for hypertension was higher for presently hypertensive females ( 76.4 percent) than it was for males ( 68.7 percent). Differences in the percents of white and black persons now with hypertension having one doctor visit or more during the year, however, were within sampling variation.

Only a small proportion of persons now with hypertension ( 8.3 percent) had to stay in bed all or most of the day for 1 day or more during the year because of this condition. Furthermore, the number of days spent in bed for this condition in the 12 -month period totaled less than 1 week for more than one-half of those persons reporting any bed days because of their high blood pressure.

The percent of currently hypertensive women with bed days for this condition was slightly higher than was the percent of men with bed days ( 9.6 compared with 6.3 percent). And proportionately more hypertensive black individuals ( 18.9 percent) reported 1 bed day or more for this condition than did the white population ( 6.5 percent).

Data on interval since last doctor visit (for any reason) are included in table 6. Highlighted below are some of the differences noted in this table among certain population groups.

Proportionately more persons now with hypertension than persons comprising the general population had a doctor visit within the past 6 months ( 79.2 compared with 61.4 percent) and within the past 12 months ( 89.5 compared with 77.1 percent).

Currently hypertensive females weré somewhat more likely to have had a recent doctor visit than were hypertensive males; within 6 months, 81.5 percent and 75.3 percent, respectively, and within the year, 91.7 percent and 85.9 percent, respectively.

In general, as age increased, the proportion of currently hypertensive persons that saw a doctor within 6 months and 12 months prior to the interview also rose. Whereas about 74 percent of hypertensive persons aged 17-44 years saw a doctor within 6 months, about 82 percent of those 65 years or older had a visit within this period. Similarly, 87.7 percent of the hypertensive population aged 17-44 visited a doctor during the year compared with 90.7 percent of persons comprising the age group 65 years and over.

No racial differences were found between the proportion of white persons and black with hypertension that saw a doctor either within 6 or 12 months of the date of interview.

Table 1. Number and percent distribution of persons 17 years of age and over by hypertension status, according to race, sex, and age; based on data collected in health interviews: United States, 1974

| Race, sex, and age | All persons 17 years and over | Hypertension status |  |  |  |  | Al1 persons 17 years and over | Hypertensiou status |  |  |  |  |

## TECHNICAL NOTES

SOURCE OF DATA. The data presented in this report were obtained from household interviews in the Health Interview Survey. These interviews were conducted throughout 1974 in a probability sample of the civilian noninstitutionalized population of the United States. During that year approximately 116,000 persons living in about $4,0,000$ households were included in the sample. The hypertension questions were asked of each household member 17 years of age and over who was identified as a "sample person." This subsample included approximately 26,000 persons.
SAMPLING. The sampling pattern for sample person selection was based on the total number of related and unrelated household members. Sample persons (approximately a one-third subsample of the actual Health Interview Survey sample) were selected by the interviewer at the time of interview. To determine which household member(s) to designate as a sample person, the interviewer referred to a preselected flashcard after listing all related and unrelated persons in the household on the questionnaire. The flashcard contained, for each household size, one or more person numbers that were to be identified as the sample person(s).

Since the estimates shown are based on a sample of the population rather than on the entire population, they are subject to sampling error. Standard errors appropriate for the estimates of the number of persons are shown in table I; standard errors appropriate for percentages are shown in table II.

Table I. Standard errors of estimates of aggregates

| Size of estimate in thousands | Standard error in thousands |
| :---: | :---: |
| 70................................................................... | 20 |
| 100.................................................................. | 24 |
| 300................................................................. | 42 |

LIMITATIONS AND QUALIFICATIONS OF DATA. When the 1974 Health Interview Survey hypertension prevalence estimates for the U.S. civilian noninstitutionalized population 17 years of age and over are compared with the 1972 Health Interview Survey hypertension estimates, marked differences are found ( 15.7 percent and 11.9 percent, respectively). Some of this variation can be attributed to improved data collection procedures implemented in 1974 as well as to definitional differences between the 2 years. These differences will be described in detail in a forthcoming report. However, evidence from other sources also indicates that some of the increase reflects a real difference resulting from a greater awareness of this condition among some respondents.

In this report, terms such as "similar" and "the same" mean that no statistical significance exists between the statistics being compared. Terms relating to differences (i.e., "greater," "less," etc.) indicate that differences are statistically significant. The $t$ test with a critical value of 1.96 ( 0.05 level of significance) was used to test all comparisons which are discussed. Lack of comment regarding the difference between any two statistics does not mean the difference was tested and found to be not significant.

Age adjustment is computed by multiplying the specific rate for each age group in the total

U．S．civilian noninstitutionalized population 17 years and over in 1974．The rate is obtained by dividing the cumulative figures previously com－ puted by the total population 17 years and over．

For a more detailed discussion of the limita－ tions and qualifications of data collected in the Health Interview Survey，see an earlier report entitled＇Current Estimates from the Health In－ terview Survey，United States，1974，Vital and Health Statistics，Series 10，No．100，DHEW Publication No．（HRA）76－1527．

NOHE5

Blood pressure measurements of persons in the civilian noninstitutionalized popula－ tion 6－74 years of age collected in the Health and Nutrition Examination Survey from April 1971 through June 1974 have been reported in Advance Data（HRA）77－ 1250，No．1，Oct．18， 1976.
