## Height and Weight of Adults 18-74 Years of Age in the United States ${ }^{\text {T }}$

The height and weight measurements in this report were obtained as a part of the Health and Nutrition Examination Survey (HANES). HANES is a program in which measures of nutritional status are collected for a scientifically designed sample representative of the civilian noninstitutionalized population of the United States in a broad range of ages, 1-74 years. ${ }^{2}$

The HANES findings are based on examinations of the 13,671 persons aged $18-74$ years from a total group of 20,749 examined persons aged 1-74 years in the 65 primary sampling units (PSU's) which make up the total sample. A nationwide probability sample of 28,043 persons was selected to be examined in 65 PSU's, which were visited between April 1971 and June 1974. The HANES nutrition examination included a

[^0]general medical examination for indicators of nutritional deficiencies by a physician, a skin examination by a dermatologist, and a dental examination by a dentist. Body measurements were taken by a trained technician; a dietary interview, consisting of a 24-hour recall of food consumption and a food frequency questionnaire, was administered; and numerous laboratory tests were performed on whole blood, serum, plasma, and urine. A description of the sampling process, HANES operation, and response rates has been published. ${ }^{2}$

Estimates in this report are based on weighted observations. The data obtained for the examined persons were inflated to the level of the total population using the appropriate weights to account for both sampling fractions and response results. National estimates of the distribution of height and weight among the U.S. population based on findings from the HANES program will be analyzed and discussed in a future report: "Height and Weight Measurements of Adults 18-74 Years: United States, 1971-74," Vital and Health Statistics, Series 11. Selected data from that report are discussed here and shown in tables 1-7.

[^1]
## PRINCIPAL FINDINGS

The mean weight of men aged 18-74 years was 172 pounds. The mean weight of men increased from 165 pounds in age group 18-24 years to 178 pounds in age group $35-44$ years. Thereafter, it decreased with age to 175 pounds in age group $45-54$ years, 171 pounds at 55-64 years, and a low of 164 pounds in the oldest age group measured, 65 years and over.

The mean weight of women was 143 pounds, 29 pounds less than that for men. The mean weight increased with age from a low of 132 pounds at $18-24$ years to a high of 149 pounds at ages $45-64$ years and then declined to 146 pounds in the oldest age group.

The cross-sectional data on body measurements of adults were obtained on different age cohorts. The age trends show the mean body measurements for successive cohorts of persons of different age groups and reflect the effect of different environmental as well as hereditary influences. The limitations of cross-sectional data are recognized in considering group age changes.

The mean height for men aged 18-74 was 69.0 inches. The highest mean height, 69.7 inches, was found in the youngest age group,

Figure 1. MEAN HEIGHT IN INCHES OF U.S. ADULTS 18-74 YEARS BY AGE AND SEX.

[^2]18-24 years, and is 2.4 inches taller than the height in age group 65 years and over, 67.3 inches. This corresponds with a small decrease in height with increasing age, which averages less than one-half inch per decade of age over the range 18-74 years.

Among women the mean height was 63.6 inches, 5.4 inches less than the mean height among men. The mean height for women was highest ( 64.3 inches), in the youngest age group, as it was for men. The mean height decreased slightly to 64.1 inches at 25-34 years, remained constant at $35-44$ years, and then declined to 63.6 inches at $45-54$ years, 62.8 inches at $55-64$ years, and 62.3 inches in the oldest age group, 65 years and over. The difference between the youngest and oldest age groups is 2.0 inches. The decrease in height with age averages less than one-half inch per decade over the age range of $18-74$ years.

In each of the five age groups in the range 18-64 years white men were taller than Negro men. The average difference between heights of white and Negro men in the same age group was about one-half inch. At age group 65 years and over, however, the mean height for Negro and white men was the same. This pattern by age and race is not observed for women. At age groups $18-24$ and $25-34$ years, white women were, on the average, 0.25 inches taller than Negro women. At ages $35-44$, Negro women were

0.1 inch taller than white women; at ages $45-54$, they were 0.2 inch taller; and at ages 65 and over, they were 0.3 inch taller. At ages 55-64 years, the mean height for both races was the same.

Mean weights increased among white men from a low of 165 pounds at 18-24 years to a high of 178 pounds at $35-44$ years. Among Ne gro men, mean weight increased consistently with age from 166 pounds at ages 18-24 years to 182 pounds at ages $35-44$ years. The mean weights of both Negro and white men decreased with age from the group 45-54 years on. Negro and white men showed little consistent difference in mean weights among the different age groups.

Data on weight by age for Negro and white women tend to parallel those seen for men, with the exception that the increase in mean weight of women continued up to the age group 45-54 years and then declined. However, at each age Negro women had larger mean weights than white women, with the differences between races being very large, averaging about 20 pounds heavier for the age groups $35-64$ years.

Although heights of U.S. adults as measured from the Health and Nutrition Examination Survey, 1971-74, were taller than those from the

Health Examination Survey (HES), 1960-62, ${ }^{3}$ the differences are numerically small. HANES data for men's heights range from less than one-half inch to an inch taller than the HES data. Corresponding values for women are from less than one-half inch to slightly more than three-quarters of an inch taller.
U.S. adults in HANES were heavier than those in HES. The HANES data on weights for men are consistently higher by an average of 6 pounds across the age range 18-74 years; for women they are higher by an average of 3 pounds for this age range.

Relatively more men and women in the most recent survey, 1971-74, are taller than those in HES, 1960-62. Fifty-one percent of the men in HANES were 69 inches or taller as compared to 38 percent in HES across the age range of 18-74 years. The corresponding values for HANES and HES for heights of 70 inches or more are 36 percent and 28 percent, respectively. In this age range, 45 percent of the women in HANES were 64 inches or taller as

[^3]

Figure 5. MEAN HEIGHT IN INCHES OF U.S. ADULTS 18-74 YEARS IN HES (1960-62) AND HANES (1971-74).

compared to 37 percent for HES. The corresponding values for HANES and HES for 65 inches and more are 30 percent and 21 percent, respectively.

The proportions of men and women whose height exceeded any other specified height may be found from the data presented in tables 4 and 6.

## TECHNICAL NOTES

The sampling plan of the Health and Nutrition Examination Survey (HANES) followed a highly stratified multistage probability design in which a sample was selected of the civilian noninstitutionalized population of the coterminous United States 1-74 years of age. Successive elements dealt with in the process of sampling were the primary sampling unit (PSU), census enumeration district (ED), segment (cluster of households), household, eligible person, and finally, sample person. The sampling design focused special attention on groups of people known to be at greater risk of malnutrition by oversampling these groups-the poor, preschool children, women of childbearing ages, and the elderly.

All height and weight data presented are based on "weighted" observations. That is, data recorded for each sample person were inflated to characterize the subuniverse from which that sample person was drawn. For each examined person, this is a product of the reciprocal of the probability of selecting the person, an adjustment for nonresponse cases (i.e., persons not examined), and a poststratified ratio adjustment which increases precision by bringing survey results into closer alignment with known U.S. population figures for 20 age, race, and sex groups as of November 1, 1972, the approximate midpoint of HANES.

[^1]:    Advance Data from Vital and Health Statistics replaces the supplements to the Monthly Vital Statistics Report as the means for early release of selected findings from the health and demographic surveys conducted by the NCHS. Most of these releases will be followed by detailed reports in the Vital and Health Statistics series.

    Provisional vital statistics as well as advance reports of final data for a year will continue to be published in the Monthly Vital Statistics Report.

    Advance Data is being distributed on the mailing keys for the Vital and Health Statistics series, and people who now receive reports from a particular series will also receive all Advance Data releases for that series. Temporarily, the mailing list for the Monthly Vital Statistics Report (MVSR) is also being used. MVSR readers who wish to continue to receive Advance Data issues, as well as other persons who wish to receive all issues, should contact:
