No. 16

BREEDING OF ANOPHELES QUADRIIMACULATUS IN DEEP WATER AND AT A DISTANCE FROM SHORE.

By H. R. CARTER, Assistant Surgeon General, United States Public Health Service.

It is generally stated that Anopheles do not breed in deep water or at a distance from shore. This is usually true because (1) such water does not furnish food for the larvae: (2) they are drowned by wave action; and (3) they are eaten by fish.

In the course of malaria surveys made by the United States Public Health Service near the United States Marine Barracks, Quantico, Va., in September, 1917, the contrary was found to be true.

Examination up to July 29 had shown no production of Anopheles in either Quantico or Chappawampsic Creek and no production of *A. quadrimaculatus* anywhere except in pools near the mouth of Creek No. 1. Since this was scanty and had not been found up to July 16, it was feared that this species would appear in Quantico and Chappawampsic Creeks as the season advanced. Being large, these creeks would warm up more slowly and hence breed later than small pools, and this species is not an early breeder.

On September 3 an examination was made of a number of houses at Quantico and *A. quadrimaculatus* were found in them in such number and distribution as to indicate an important source to the northeast of the village. In addition 442 mosquitoes were taken in an isolated group of tents one-third mile distant from the lower part of the Chappawampsic. No other water not under control was within a mile.

Examination of Quantico and Chappawampsic Creeks was made by boat by Mr. Messer of the Virginia State Board of Health and myself. In both creeks there were large masses, acres in extent, of "floatage" over the wild celery (*Vallisneria spiralis*).

This plant was growing in water from $2\frac{1}{2}$ feet to over 6 feet deep and extended in places from one-quarter to possibly one-half mile from shore. Its long blades floated just level with the surface of the water rising and falling with the tide and pointing down the current. The "floatage" was formed mainly of the broken pieces of these blades—they are quite fragile—and an enormous amount of pollen of the same plant; it was then in flower. In a

few places the "floatage" was bound together by a growth of algae, but mainly adherent without it. In these creeks there was the heaviest breeding of *Anopheles quadrimaculatus* I have ever seen over a large area. The patches of "floatage" were measurable in acres and fractions of an acre rather than in square yards. In Quantico Creek they were at both sides of the channel, but none within 300 feet, say, of the shore. In Chappawampsic Creek they were mainly near the mouth and on the side next to the camp. Here they were within half a mile, maybe less, of the tents in which we found the Anopheles and were most probably their source. Quantico Creek is about a mile wide where this "floatage" was found. Chappawampsic is about 1½ or 2 miles wide at its mouth. We estimated the average number of larvae per dip at 8, but one dipper took 52. They were of all sizes, and pupæ were also present. In addition to the breeding in this "floatage" there was breeding in some of the lotus beds, where the leaves of this plant fell into the water and adhered together as they decayed. Where the leaf stood up above the water there was no breeding. The same conditions, breeding in floatage in deep water, had been noted on Broad River, S. C., and other places in our work on Impounded Waters, but none so spectacular as this.

In all of these cases the matting of the "floatage" prevented the breaking of the waves, which passed through it in long smooth swells, and furnished a perfect protection against fish. It must also have provided a good food supply.

The problem of the control of this breeding is a very difficult one.

EFFECT OF ANOPHELES PUNCTIPENNIS ON THE NATURAL CONVEYANCE OF MALARIAL FEVER.

By H. R. CARTER, Assistant Surgeon General, United States Public Health Service.

There is no question that *A. punctipennis* is capable of conveying malarial fever. King first (1915) showed that mosquitoes of this species were readily infectible and that the malaria parasite underwent complete sporogenous development in them. Mitzmain later (1916) produced malarial fever in men by the bites of infected mosquitoes of this species. To what extent they convey malaria *in nature*, however, is not determined.

It has been shown (Public Health Bulletin No. 79) that this mosquito is rarely found in residences—houses occupied by men—in the day time. Where both species are breeding to the same extent *A. quadrimaculatus* is found in such houses in far greater numbers than *A. punctipennis*. If this is because *A. punctipennis* do not enter the

residence to feed; it would imply that they are less efficient as vectors of malaria than *A. quadrimaculatus*. It may be, however, that they enter residences at night, feed and leave before morning. Such evidence as we have is against this, but it is not enough to be convincing. It was purposed to determine this point last summer, but owing to the war this study could not be carried out. Indeed, observations to determine the general problem "To what extent is *A. punctipennis* a vector in nature" had been planned from several sides, biological and epidemiological, but were necessarily abandoned when the extra-cantonment work was taken up. The following epidemiological observations, however, bearing on this subject, were made:

A malaria survey was made in August 1917 of Camp Meade, Md., and its environment—about 18 square miles. Eight residences gave a history of malarial fever in 1916 and 1917 at four places. Examination of 74 places breeding Anopheles showed 5 of them producing *A. quadrimaculatus* or *A. crucians*. The remaining places were breeding only *A. punctipennis*. *Punctipennis* were also found in three of the other places with the other species.

Note that malaria was reported in houses near all the places producing *Anopheles quadrimaculatus* or *crucians* except one.¹ Of some 300 houses where the malaria history was taken, the great majority of which were near places producing *punctipennis*, only one reported malaria. The country was, as seen from the number of houses, very thickly settled, mainly by whites, and in the part most thickly settled the breeding of *Anopheles* (*punctipennis*) was as general as I have ever seen. I don't mean as profuse, although it was free and in places profuse.

It is obvious that the diagnosis of malaria based on the statements of patients can not be accepted without reserve, but at four of these houses (all near breeding places of *A. quadrimaculatus* or *A. crucians*) the history of repeated chills and fevers, given by intelligent people, was very clear, and Derivaux states that he found a number of such cases (in 1915) near the other place breeding *quadrimaculatus*. The statement of those claiming freedom from malaria can, I think, generally be accepted, as it involved freedom from any kind of sickness. The census of the houses was made by the State board of health, but special inquiries, at five of the houses, were made by myself.

In this locality, then, the production of *A. punctipennis* in large number and adjacent to many white people was not associated with malarial fever, while that of *A. quadrimaculatus* and *A. crucians* was.

This may be correlated with our observations at Greenville, S. C., in 1914 and 1915. In June, August, and September a stream run-

¹ There was a house near this place, but it probably was not visited or there was no one at home when it was visited.

ning through the heart of this town was absolutely swarming with *A. punctipennis* larvæ and the imagos were abundant in culverts, spring inclosures, etc. Yet Greenville was practically free from malaria. There was some malaria, but it was scarcely a sanitary problem. The same was true of Rock Hill, S. C.: a large production of *A. punctipennis* and only a very moderate amount of malaria. The same appears to be true of the country around Atlanta. Grimm, of the Public Health Service, states that in a large number of blood specimens examined at Spartanburg, S. C., during two and one-half years, he failed to find the malaria parasites except in cases that had recently come from malaria sections. Yet Le Prince reports *A. punctipennis* breeding freely in this section last fall, and I think this was true in 1914 also.

During the investigation of impounded waters some country neighborhoods were found with a large number of *punctipennis* and only a moderate amount of malaria, contrasted with communities in which *quadrimaculatus* was prevalent and malaria decidedly common. For instance, a survey of the Valley of Broad River, S. C., from Dawkins to Blair, was made by Griffitts in 1916. *Punctipennis* was breeding freely in all of this section, which, however, was not considered as malarious (measured by the standard of this section) except at the Buckhead Settlement. Here it was prevalent, notoriously so, and here *A. quadrimaculatus* was breeding freely in some large ponds. More imagoes of this species were taken in the first house examined at Buckhead than in the 12 days' work in the *punctipennis* district. Several somewhat similar instances could be given from these investigations. Observations consistent with the above have been made at other places.

I have never found malaria prevalent where only *punctipennis* was breeding, but Brumfield of Virginia has reported quite an outbreak of malaria where this was the only species. There was also a sharp epidemic at Greenville, S. C., in 1912, although whether *punctipennis* was the only form then present is not known.

The above report of conditions about Camp Meade is made so that other men may be encouraged to record observations of similar (or contrasting) conditions, i. e., the relation of the prevalence of *A. punctipennis* to the presence or absence of malarial fevers. The definite determination of the efficiency of this species as a vector *in nature* compared with *A. quadrimaculatus* and *A. crucians*, is of very great importance to the sanitarian. If it is not a vector of serious sanitary importance—for which there is certainly some evidence—we will avoid undertaking the very large amount of work required for the control of its production. Its breeding habits are quite different from those of *A. quadrimaculatus* (and to a lesser degree from those of *A. crucians*) both in character of place and in season, and special

measures are required for the control of this species not needed for the others. Over the whole United States the cost of these and other measures for controlling *punctipennis* would run into many millions each year, which should not be expended if the malaria averted by them—for *punctipennis* unquestionably does convey some malaria—causes less loss than would the expense of averting it. To spend a dollar in sanitation and get less than one hundred cents' benefit is not only bad business, but bad sanitation.

To what extent each of the three species of *Anopheles* most common east of the Rocky Mountains, *A. quadrimaculatus*, *A. crucians*, and *A. punctipennis*, is a factor in the *natural* conveyance of malaria is possibly the most important of our field problems.

PREVALENCE OF DISEASE.

No health department, State or local, can effectively prevent or control disease without knowledge of when, where, and under what conditions cases are occurring.

DISEASE CONDITIONS AMONG TROOPS IN THE UNITED STATES.

The following data are taken from telegraphic reports received in the office of the Surgeon General, United States Army, for the week ended April 5, 1918:

Annual admission rate per 1,000 (disease only):

All troops	1,685.1
National Guard camps	1,478.3
National Army camps	1,943.7
Regular Army	1,518.5

Noneffective rate per 1,000 on day of report:

All troops	47.8
National Guard camps	41.4

Noneffective rate per 1,000 on day of report—Continued.

National Army camps	54.3
Regular Army	43.5

Annual death rate per 1,000 (disease only):

All troops	11.6
National Guard camps	5.9
National Army camps	14.1
Regular Army	13.6

New cases of special disease reported during the week ended Apr. 5, 1918.

Camps.	Pneumonia.	Dysentery.	Malaria.	Venereal.	Measles.	Meningitis.	Scarlet fever.	Deaths.	Annual admission rate per 1,000 (disease only).	Noneffective rate per 1,000 on day of report.

CURRENT STATE SUMMARIES.

Connecticut.

From Collaborating Epidemiologist Black, by telegraph, for week ended April 13, 1918:

Cerebrospinal meningitis: Bridgeport 1, Waterbury 2.

Illinois.

From Collaborating Epidemiologist Drake, by telegraph, for week ended April 13, 1918:

Smallpox: One hundred and three; of which Chicago 4, Honeypoint Township, Macoupin County 5, Alton 22, Peoria 13, Quincy 16, Belleville 5, East St. Louis 8. Scarlet fever: One hundred and six; of which Chicago 49. Meningitis: Chicago 12, Wheaton 1, Winfield Township, DuPage County 1, West Warren Township, Williamson County 1, Virden 4, Minook Township, Woodford County 2. Poliomyelitis: Chicago 6, Beardstown 1.

Indiana.

From the State Board of Health of Indiana, by telegraph, for week ended April 13, 1918:

Smallpox: Epidemic Crown Point, Rushville. Measles: Epidemic Wawaka. Scarlet fever: Epidemic Newcastle. Epidemic meningitis: Two cases Charleston, Clark County. La Grippe: Epidemic Fort Wayne, Anderson, Muncie.

Kansas.

From Collaborating Epidemiologist Crumbine, by telegraph, for week ended April 13, 1918:

Meningitis: McLouth 1. Smallpox (10 or more cases): By counties—Brown 15, Butler 15, Decatur 10, Reno 27, Seward 11, Woodson 10; by cities—Kansas City 20, Wichita 18, Ottawa 12, Pottawatomie 10. Scarlet fever (over 10 cases): Riley County 11, Topeka city 20. Scarlatina prevalent over entire State.

Louisiana.

From Collaborating Epidemiologist Dowling, by telegraph, for week ended April 13, 1918:

Meningitis (excluding Rapides Parish): De Soto Parish 1.

Massachusetts.

From Collaborating Epidemiologist Hitchcock, by telegraph, for week ended April 13, 1918:

Unusual prevalence. Diphtheria: Malden, 17. German measles: Brookline, 45; Chelmsford, 8; Mansfield, 23; Manchester, 10; Rockland, 12. Measles: Brookline, 34; Chelsea, 38; Haverhill, 50; Waltham, 58. Scarlet fever: Colerain, 7.

Minnesota.

From Collaborating Epidemiologist Bracken, by telegraph, for week ended April 13, 1918:

Smallpox (new foci): Lyon County, Stanley Township, 1; Mower County, Austin Township, 1; Norman County, Strand Township, 3; Renville County, Bandon Township, 3.

Nebraska.

From the State Board of Health of Nebraska, by telegraph, for week ended April 13, 1918:

Poliomyelitis: One case, Tilden. Typhoid fever: One case, Davenport. Smallpox: Red Cloud, Emerson, Henderson, Broken Bow, Scottsbluff, Atkinson, Upland, Humphrey, Omaha, Lincoln, Tecumseh, Antioch, Holland, Brewster, Murdock, Tamora, Culbertson, Wayne. Scarlet fever: Pakmer, Omaha, Emerson, License. Measles: Scottsbluff, Omaha, Bee, Leigh. Diphtheria: Shelby, Geneva. German measles: Lyons. Septic sore throat: Lyons.

New Jersey.

From Collaborating Epidemiologist Bowen, by telegraph, for week ended April 13, 1918:

Unusual prevalence. Measles: East Orange, Bayonne, Paterson. Whooping cough: Paterson.

South Carolina.

From Collaborating Epidemiologist Hayne, by telegraph, for week ended April 15, 1918:

Epidemic meningitis: Six cases week ended 15th.

Virginia.

From Collaborating Epidemiologist Traynham, by telegraph, for week ended April 13, 1918:

Smallpox: By counties—Pulaski 12, Lee 1, Smyth 1, Caroline 2, Russell several, Spottsylvania several, Middlesex 1, Wise 1, Pittsylvania 1, Carroll 16, Suffolk 1, Newport News city 6. Cerebrospinal meningitis: By counties—Lunenburg 1, Prince William 1, Sussex 2, Roanoke 1, Prince George 1, Norfolk 1; Newport News city 4, Richmond city 1. Poliomyelitis: By counties—Accomac 1, Mecklenburg 1.

Washington.

From Collaborating Epidemiologist Tuttle, by telegraph, for week ended April 13, 1918:

Unusual prevalence. Scarlet fever: Prevalent Kent, King County. Smallpox: Thirteen cases in quarantine at Arlington, Snohomish County. Scarlet fever: Twenty-nine cases in Tacoma.
