

PUBLIC HEALTH REPORTS

VOL. 35

JANUARY 30, 1920

No. 5

INFLUENZA.

PREVALENCE IN THE UNITED STATES.

Reports from State and city health officers throughout the country indicate an increase in the number of reported cases of influenza. The disease is generally mild, and some reports state that many cases are not seen by physicians.

The following table shows the number of cases of influenza reported by State health officers for the week ended January 24, 1920, as compared with the reports for the week ended January 17. These reports are received by telegraph and are incomplete, but the general increase in the number of cases from so many States is significant.

Influenza cases reported by State health officers.

The summary herewith presented of deaths from all causes in certain large cities during the week ended January 24 and preceding weeks is, as usual, a reproduction of data published by the United States Census Bureau in the Weekly Health Index.

In the summary of deaths from influenza and pneumonia, which follows, the data used have likewise been taken from the Weekly Health Index except as otherwise noted. In certain instances where data given in the Weekly Health Index are incomplete, the figures given for deaths from influenza and pneumonia have been compiled from reports made to the Public Health Service by State health authorities, or from unofficial reports in the daily press. These figures are necessarily subject to correction, but are presumably sufficiently accurate for preliminary use.

As a basis for comparing mortality during the specified weeks with what may be considered the normal mortality from these diseases, a weekly average for each city has been computed from statistics of monthly mortality during the seven-year period, 1911 to 1917, inclusive. The number of deaths in the corresponding month of

the year during this period having the median number of deaths has been used as the base from which a weekly average has been computed. While no allowance has been made by this method for increases in population since the year taken as the base, it appears from such study as has been made of the data that the averages given represent a more nearly normal mortality than do averages based on mortality during the year 1917.

A distinct increase in the mortality from influenza and pneumonia is noted in Chicago, Kansas City, Milwaukee, New York, San Francisco, St. Louis, and Washington, with a less definite but probably significant increase in Newark. There can be no doubt that these increased mortality rates reflect the epidemic prevalence of influenza in these cities.

Deaths from all causes in certain large cities of the United States during the week ended Jan. 24, 1920, infant mortality (per cent), annual death rates, and comparison with corresponding week of preceding years.

¹2,055 cases of influenza and 646 cases of pneumonia were reported during the preceding 7 days.

WATER-BORNE TYPHOID AND SPRING FRESHETS.

In no other common communicable disease prevalent in this country have sanitarians so frequently achieved such effective control as in the case of typhoid fever. When one considers what an enormous reduction in the prevalence of typhoid fever has been accomplished, especially by many of the cities in this country, he can not but marvel at the public indifference and neglect with which other communities still tolerate potentially dangerous water supplies, insanitary disposal of excreta, and other common sources of typhoid infection.

So far as water-borne typhoid infection is concerned, now is the time for health officers to be especially alert. Many of the well-known extensive water-borne epidemics of typhoid fever have occurred during the winter and early spring, being associated in the majority of instances with extensive rains and freshets which washed infected material into the water supply. "Thus," to quote Rosenau, "we have the water-borne epidemic in Plymouth, Pa., in 1885, which began with the spring thaw and was doubtless caused by the frozen accumulation of typhoid excrement from a single case. Very similar to the Plymouth outbreak was that at New Haven, Conn., in 1901. Several similar epidemics occurred in the winter time in Chicago, one in January, 1890, another in January, 1896, and one in March, 1891. Another striking instance is the epidemic in Newark, N. J., in February, 1899, and one in December, 1891." In New York City an extensive outbreak of water-borne typhoid fever occurred in February and March, 1907. Such examples could be multiplied from European and other sources.

The lesson to be derived from these outbreaks is plain. Potentially dangerous sources of water supply should be made safe, and health authorities should insist that communities provide for safe disposal of human excreta. Practically all surface water supplies used in an unfiltered condition and not disinfected, should be regarded

as potentially dangerous. Even when they are filtered or disinfected however, careful attention is required to make sure that the process is effective. An instructive lesson on this phase of the problem was afforded by the outbreak of typhoid fever in Herkimer, N. Y., reported in the Public Health Reports last year.

Mr. Health Officer:

Has your community a safe water supply? How do you know that it is safe? Have you *recently* made a sanitary survey of the sources of the supply to make sure that it is not potentially dangerous? Do you have bacteriological tests made frequently and regularly? Do you permit a large proportion of your citizens to use water from wells which may be polluted? Is your town adequately sewered or are there still many homes with cesspools and insanitary privies? If your town is small and not provided with waterworks, it is possible that insanitary privies and unsafe methods of disposal of human excreta are polluting your wells.

Now is the time to take steps to prevent the threatened outbreak of water-borne typhoid fever:

CONJUGAL TUBERCULOSIS.

One of the earliest infectious diseases to have its bacterial cause definitely established, and easily the disease concerning which the greatest amount of scientific research, laboratory, epidemiological, clinical, and sociological, has been undertaken, tuberculosis still remains one of the chief problems confronting health authorities. Moreover, in order to secure control of this disease, it is quite imperative that correct answers be supplied to a number of important questions. Of these, perhaps the most important relates to the question of infectivity, for at the present time it is generally recognized that mere presence of the tubercle bacillus is not synonymous with infection. In this connection students of tuberculosis have repeatedly called attention to the relative infrequency of conjugal infection in tuberculosis. In the case of tuberculosis, numerous investigators have noted that phthisis in both husband and wife is very rare, despite the fact that they probably come into more intimate contact than even father and child.

Following an excellent summary of conjugal tuberculosis, Fishberg in the latest edition of his work "Pulmonary Tuberculosis" comes to the following conclusions:

"We have dwelt on these facts because they are very important points in phthisiogenesis: (1) Tuberculous infection can only occur once; and (2) that phthisis evolves only in persons who are for one reason or another predisposed to the disease. Inasmuch as the

nonphthisical consort has already been infected with tubercle bacilli during childhood, all new opportunities for reinfection by cohabitation with a consumptive consort are of no avail to produce phthisis. It is his or her constitution that determines whether consumption will develop and not the opportunities for reinfection."

The correctness of the view expressed above has recently been challenged. In an interesting article entitled "Conjugal Tuberculosis," published in the *Lancet* (Oct. 4, 1919), E. Ward, M. D., tuberculosis officer for South Devon, gives the results of an inquiry extending over a period of 5 years, and relating to 156 cases in which the mate of a tuberculous husband or wife was examined. The results of these examinations are tabulated as follows:

CHART I. *Results of examination of contacts of tuberculous patients, husband and wife.*

	Number exam- ined.	Tuber- culous.	Suspect.	Nega- tive.	Percentages.		
					Tuber- culous.	Suspect.	Nega- tive.
Wives (husband first notified).....	120	66	12	42	55	10	35
Husbands (wife first notified).....	36	25	4	7	69	11	20
Total.....	156	91	16	49	58	10	32

"In deciding to which category a contact belongs, the examination was not made so punctiliously that few could escape the net; two or more definite indications were required. Crepitations at one apex alone would not be called tuberculosis, but crepitations at one apex, plus a history of hæmoptysis, would be so called. Similarly dullness and crepitations at one apex would be classed as tuberculosis; and also failing health, hæmoptysis, and dullness, with crepitations, at one base. If the signs found were suggestive, but not sufficiently conclusive, the contact was classed as suspect.

"Comparing now the results of examining contacts other than husband and wife; out of 1,067 examined, 219 were tuberculous, 284 suspect, and 564 negative; or, roughly, 20 per cent, 27 per cent, and 53 per cent (Chart II). Taking as a further control the contacts of cases seen for an opinion and diagnosed nontuberculous, either at the time of the first visit or later, out of 81 examined, 4 are found to be tuberculous, 7 suspect, and 70 negative; or in percentages, 5 per cent, 8 per cent, and 87 per cent (Chart III). Cases of definite surgical tuberculosis, and their contacts, are included, but the number of such cases was relatively small."

After discussing the results of this investigation, the author concludes as follows:

"Well knowing the difficulties in the way of any statistical investigation such as this, I make no claim that the present contribution is a final settlement of the question, but am sure that this important subject should be reconsidered in the light of the greatly increased material now available. On the opinion generally held regarding infection the success or failure of all our antituberculosis work depends. Either we take the fatalistic view of a universal infection and family predisposition (I almost wrote predestination), and therefore direct our efforts to help the tuberculous individual, or we look upon the disease as infectious, and take means to prevent it by isolating highly infective cases, there being as yet no method of universal vaccination against tuberculosis. I estimate that over 50 per cent of all cases seen are due to direct personal infection, and am therefore a strong advocate of preventive measures."

With the large number of well-organized tuberculosis clinics at work in this country, it should not be difficult to obtain a large amount of accurate statistical information to determine which view represents the true condition. Further studies along this line are certainly desirable, for the question at issue involves one of the most fundamental points in the whole tuberculosis campaign.

DIVISION OF VENEREAL DISEASES, NOVEMBER 1- DECEMBER 31, 1919.

The accompanying table covers the activities of 253 of the clinics operating under the joint control of the United States Public Health Service and State boards of health, for the months of November and December, 1919.

This table shows that during that time there were 17,925 new admissions, making a total of 52,343 under treatment. There were 236,036 treatments administered to the patients under the care of these clinics, of which 41,848 were the administration of arsphenamine.

A table showing the number of cases of venereal diseases reported by State boards of health for November and December, 1919, is also given.

Census of patients under care of 253 of the clinics operated by the United States Public Health Service and State boards of health, for the months of November and December, 1919.

¹ Annual rates per 1,000 estimated population.

² "A" indicates data for the corresponding week of the years 1913 to 1917, inclusive. "C" indicates data for the corresponding week of the year 1917.

³ Population estimated as of July 1, 1913.

⁴ Data are based on statistics of 1915, 1916, and 1917.

Summary of information received by telegraph from industrial insurance companies for week ended Jan. 17, 1920.

Policies in force.....	41,958,459
Number of death claims.....	8,564
Death claims per 1,000 policies in force, annual rate.....	10.6

PREVALENCE OF DISEASE.

No health department, State or local, can effectively prevent or control disease without knowledge of when, where, and under what conditions cases are occurring.

UNITED STATES.

CURRENT STATE SUMMARIES.

Telegraphic Reports for Week Ended Jan. 24, 1920.

These reports are preliminary, and the figures are subject to change when later returns are received by the State health officers.
