WEIL-FELIX TEST FOR TYPHUS FEVER.

THE WEIL-FELIX REACTION IN THE DIAGNOSIS OF TYPHUS FEVER AS USED AT THE NEW YORK QUARANTINE STATION.

By JOHN E. HOLT-HARRIS, Scientific Assistant, and S. B. GRUBBS, Surgeon, United States Public Health Service.

Physicians with experience in maritime quarantine agree that the clinical diagnosis of typhus fever, while frequently difficult, is, some times, impossible, and will welcome a reliable laboratory test for this disease. The Weil-Felix test, first described in 1918, has been in use at the New York quarantine station for more than two years and has given satisfactory results. It has been of great value in deciding obscure cases, thus increasing the protection to the country and shortening the delay to commerce and the traveling public. We believe our experience warrants us in recommending the use of this test in quarantine practice, and elsewhere, when there is a question of typhus fever. We also wish to submit the simple technique worked out in the laboratory at this station.

The Weil-Felix reaction depends upon the agglutinating property of typhus serum upon certain strains of the Proteus group isolated in 1915 by Weil and Felix from stool and urine of typhus fever patients, and designated by them X 2 and X 19. The exact nature of this phenomenon need not be discussed for our purposes, nor is it necessary to review the literature. In this work we have used exclusively the strain X 19.

Since February 3, 1920, 1,698 tests have been made at the New York Quarantine Station. Twenty of these tests were made upon clinically positive typhus patients, 43 upon atypical or clinically doubtful cases, 737 upon cases of various acute diseases, 264 upon persons suffering from chronic diseases, and 634 upon apparently normal persons. In all but two of the clinically or atypically positive cases of typhus fever (CP-SH, as shown in the table), the first tests were positive. These two negative tests were made early in the disease, when, as is well known, the reaction is frequently not manifest. Later, both became positive. All cases giving a positive reaction were undoubtedly typhus fever.

We employ as a routine technique at this station, first, a tentative test, which, if positive in dilution $\frac{1}{20}$, is followed by a second or confirmative test. The tentative test is usually made on shipboard as follows: Prick the suspect's ear and touch the resultant drop of blood with a clean glass slide near one end. Allow the blood to coagulate. With a 2 mm. loop, place at the other end of the slide one loopful of normal saline solution, three loopfuls in the center of the slide and four loopfuls near the drop of blood, as shown in the accompanying figure. Mix the blood with the four drops of saline near it, using a wire bent at right angles instead of the loop. Separate the clot and discard it. Carry one loopful from this dilution to the three drops of saline and mix, and carry a loopful to the single drop and mix. Thus, there are obtained three dilutions of serum of approximately $\frac{1}{5}$, $\frac{1}{20}$, $\frac{1}{40}$. The mixing should be done up and down, from edge to edge of the slide, in as narrow a channel as possible in order to conserve the body of the fluid. When this is done, sterilize the loop in the flame of an alcohol lamp, pick up a small amount of the culture X19 from a 24-hour agar slant and place a little at the margin of each dilution. Emulsify first, dilution $\frac{1}{40}$, next $\frac{1}{20}$, and finally $\frac{1}{5}$, going directly from one dilution to the other without flaming the loop. Pick up the slide and rotate it slowly upon its long axis against a dark background. Agglutination is shown by the appearance of white flocculi which increase in size and are readily discernible in the stream of fluid as it flows in its narrow channel across the slide. Prompt and complete clumping, especially in dilutions of $\frac{1}{40}$, points to typhus fever. If no clumping take place within three minutes, add to dilution $\frac{1}{40}$ a small amount of typhus serum as control, or, if typhus serum is not available, add the serum of a rabbit immunized against X19.

Where the tentative test is positive, the patient is bled from the basilic vein and the confirmative test is made in the laboratory as follows: Serum dilutions of $\frac{1}{10}$, $\frac{1}{20}$, $\frac{1}{40}$, etc., to $\frac{1}{1280}$ are made in Wassermann tubes. Nine-tenths c. c. of normal saline solution is placed in the first tube and 0.5 c. c. in each of the other tubes, using a 1 c. c. pipette. Add 0.1 c. c. of the separated serum to the 0.9 c. c. saline of the first tube, using a 0.2 c. c. pipette, thus making a dilution of $\frac{1}{10}$. Successive dilutions of $\frac{1}{20}$, $\frac{1}{40}$, etc., are made by the addition of 0.5 c. c. of a dilution to the succeeding 0.5 c. c. of saline, using the original 1 c. c. pipette until the series is complete. Now, with the same pipette, deliver on glass slides, from right to left as shown in the diagram, a drop of each of three dilutions beginning with the highest dilution, and proceed as in the tentative test. By this method agglutination in dilution $\frac{1}{40}$ may be regarded as diagnostic of typhus fever, and the highest agglutinating titer of the serum is quickly determined.

1. Blood drop with necessary amounts of saline solution for approximate dilutions of $\frac{1}{10}$, $\frac{1}{20}$, $\frac{1}{40}$.
2. Dilutions of $\frac{1}{10}$, $\frac{1}{20}$, $\frac{1}{40}$ with Proteus X 19. Culture below ready to mix.
3. Emulsions showing negative reaction.
4. Emulsions showing positive reaction, $\frac{1}{10}$, $\frac{1}{20}$, $\frac{1}{40}$.

A table is presented herewith showing certain selected cases diagnosed at the New York quarantine station. In general, it may be said that those classed as typical cases would have been diagnosed by our regular clinical methods of examination. However, those classed as atypical might have been admitted unobserved; and, on the other hand, the clinically suspected cases, such as are shown in the third part of the table, if held for observation, would have caused serious delay to the ships, whereas the test immediately excluded typhus fever. Therefore, a diagnosis of typhus fever with us invariably depends upon the Weil-Felix reaction.

CONCLUSIONS.

1. The Weil-Felix reaction is of great value to confirm or eliminate the diagnosis of typhus fever.
2. For the purpose of maritime quarantine, the modified Weil-Felix reaction test devised at this station is reliable, and greatly expedites shipping when there is a question of typhus fever.
3. At the New York quarantine station a positive Weil-Felix reaction is regarded as diagnostic of typhus fever. After the first few days (3 to 7) of the illness, a negative reaction is accepted as the strongest evidence against this disease.

THE NOTIFIABLE DISEASES.
PREVALENCE DURING 1921 IN CITIES OF 10,000 TO 100,000.

ANTHRAX, CEREBROSPINAL MENINGITIS, DIPHTHERIA, INFULENZA, MALARIA, MEASLES, PELLAGRA, PNEUMONIA (ALL FORMS), POLIOMYELITIS (INFANTILE PARALYSIS), RABIES IN ANIMALS, RABIES IN MAN, SCARLET FEVER, SMALLPOX, TUBERCULOSIS, (ALL FORMS AND PULMONARY), TYPHOID FEVER, AND TYPHUS FEVER—CASES AND DEATHS REPORTED, 1921; INDICATED CASE AND DEATH RATES PER 1,000 POPULATION; FATALITY RATES PER 100 CASES; AND MEDIAN NUMBER OF CASES REPORTED DURING PRECEDING YEARS.

The tables shown on the following pages were compiled from data furnished by the health officers of cities. Requests for information were sent to all cities of the United States having 10,000 population or more. The data for cities having more than 100,000 population were published in the PUBLIC HEALTH REPORTS; volume 37, No. 23, June 9, 1922.

The present article contains reports from cities having between 10,000 and 100,000 population which responded to the request for information. It is believed that practically all cities are included which have records of morbidity from communicable diseases which are of value for statistical purposes.

Estimates of population for dates later than the census of January 1, 1920, are not available. The population figures given in the tables are the preliminary figures furnished by the Bureau of the Census as of January 1, 1920. The case and death rates were computed directly from these figures and are subject to correction when estimates of population for post-censal years are obtainable. As nearly all cities have increased in population since 1920, the rates in most instances are higher than the corrected rates will be.

Medians¹ of the total number of cases reported annually during the years 1914 to 1920 are given for cerebrospinal meningitis, diph-

¹ The median has been defined as the magnitude of the middle item in an array. If the number of cases reported are arranged so that the greatest number reported in any one year is first, the second greatest number is second, and so on, then the number of cases in the center of the array is the median. The following illustration shows the method followed when data for five years are available: In a city reporting 60 cases in 1915, 79 cases in 1916, 71 cases in 1917, 58 cases in 1918, and 53 cases in 1919, the median is 60 cases.

theria, measles, poliomyelitis (infantile paralysis), scarlet fever, small-pox, and typhoid fever. The column headed "Number of years" shows the number of years for which data were available. For pellagra, data were available only for the years 1915 to 1920, inclusive.

For all diseases except anthrax, rabies, and typhus fever, there is given either the fatality rate per 100 cases or the number of cases reported for each death registered.

In comparing the figures for 1921 with the medians for preceding years, it should be borne in mind that there has been a gradual improvement in the reporting of communicable diseases during the last few years. An increase in the number of cases reported may be due to better reporting of the particular disease rather than to an increase in the number of cases existing.

In studying these tables it should be kept in mind that a relatively large number of reported cases of a communicable disease as indicated by a high case rate (and more especially when accompanied by a relatively small number of deaths, as indicated by a low fatality rate) usually means that the health department of that city is active and that the cases of the disease are being well reported by the practicing physicians. It does not usually mean that the disease is more prevalent in that city than in other cities. A high fatality rate may mean that the disease was unusually virulent in a city, that the physicians did not treat the disease in that city with the success usual elsewhere, or that the practicing physicians did not report all of their cases to the health department. On the other hand, an unusually low fatality rate may be due to the fact that the disease in the city was unusually mild, that the physicians treated it with unusual success, that the practicing physicians reported their cases satisfactorily, or that the registration of deaths was incomplete or the assignment of the causes of death inaccurate.

Cities in which no cases of a certain disease were reported are not included in the table for that disease.

REGULATION REQUIRING DENATURING OF UNSOUND EGGS UPHELD.

An order or regulation of the health commissioner of the city of Boston, requiring the denaturing of unsound eggs in all establishments where eggs are handled for food or mechanical purposes, has been upheld by the Supreme Court of Massachusetts.¹ The court stated in the opinion that "A regulative measure may require precautions to avoid possible danger, as well as to restrict conditions actually harmful."

DEATHS DURING WEEK ENDED JULY 1, 1922.

Summary of information received by telegraph from industrial insurance companies for week ended July 1, 1922, and corresponding week, 1921. (From the Weekly Health Index, July 6, 1922, issued by the Bureau of the Census, Department of Commerce.)

CITY REPORTS FOR WEEK ENDED JUNE 24, 1922.

CEREBROSPINAL MENINGITIS.

The column headed "Median for previous years" gives the median number of cases reported during the corresponding weeks of the years 1915 to 1921, inclusive. In instances in which data for the full seven years are incomplete, the median is that for the number of years for which information is available.

POLIOMYELITIS (INFANTILE PARALYSIS).

The column headed "Median for previous years" gives the median number of cases reported during the corresponding weeks of the years 1915 to 1921, inclusive. In instances in which data for the full seven years are incomplete, the median is that for the number of years for which information is available.

FOREIGN AND INSULAR.

GREECE.

Cholera—Quarantine Station—Saloniki.

Under date of June 17, 1922, the occurrence, since June 7, 1922, of 30 cases of cholera with 11 deaths, was reported at St. George's Island quarantine station, Saloniki, Greece. The cases occurred among passengers of a vessel which arrived at Saloniki with Russian refugees on board.

JAMAICA.

Alastrim.

During the two weeks ended June 10, 1922, 36 new cases of alastrim were reported in the island of Jamaica. During the week ended June 17, 1922, 234 new cases of alastrim were reported in the island and the disease was stated to be epidemic.¹ The occurrence was reported in seven parishes, the greatest number of cases in one locality, viz, 187, being reported in St. James Parish.

Typhoid Fever—Kingston and Vicinity.

During the three weeks ended June 17, 1922, 15 cases of typhoid fever were reported at Kingston and 48 cases in the surrounding country.

NEWFOUNDLAND.

Mortality, 1921—Decrease in Mortality from Tuberculosis.

During the year 1921, 3,497 deaths were reported in the island of Newfoundland. Of this number, 389 were due to tuberculosis, a decrease of 110 from that for the year 1920. This decrease is explained as the result of work in combating the disease. The death rate per 1,000 of the population was stated to be the lowest recorded for this disease in the colony, viz, 1.47.

Deaths By Age Groups.

The following table gives the number of deaths by age groups for the years 1920 and 1921:

Age (years).	1920	1921	Age (years).	1920	1921
Under 1.....	1,149	893	60 to 70.....	370	353
1 to 5.....	351	284	70 to 80.....	517	421

10 to 15.....	103	98	90 to 100.....	49	53
15 to 20.....	174	152	100 and over.....	1	2
20 to 30.....	378	312	Not given.....	16	10
30 to 40.....	268	196			
40 to 50.....	206	162	Total.....	4,259	3,497
50 to 60.....	239	186			

¹ Public Health Reports, July 7, 1922, p. 1672.

DEATHS FROM CERTAIN COMMUNICABLE DISEASES—1911, 1920 AND 1921.

The number of deaths from the more important communicable diseases for the years 1911, 1920, and 1921, were as follows:

Disease.	Year.		
	1911	1920	1921
Bronchitis.....	119	101	69
Diphtheria and croup.....	31	82	69
Influenza.....	56	128	44
Measles.....	82	6	0
Pneumonia.....	149	212	153
Tuberculosis, pulmonary.....	694	499	389
Whooping cough.....	66	31	130

Population, 1912, estimated 237,500; population, Census of 1921, 259,317.

RUSSIA.

Communicable Diseases—Esthonia—Lettonia—April, 1922.

Communicable diseases have been reported in the Provinces of Esthonia and Lettonia, for the month of April, 1922, as follows:

Disease.	Cases.	
	Esthonia.	Lettonia
Cerebrospinal meningitis.....	1	1
Diphtheria.....	43	51
Measles.....	465	71
Scarlet fever.....	38	155
Smallpox.....	2	21
Tuberculosis.....	150
Typhoid fever.....	31	47
Typhus fever.....	15	1275
Whooping cough.....	32

¹ Recurrent typhus, 12 cases.

VIRGIN ISLANDS.

Contagious Diseases—May, 1922.

The occurrence of contagious diseases in the Virgin Islands during the month of May, 1922, has been reported as follows:

Island and disease.	Cases.	Remarks.
In St. Thomas and St. John:		
Chicken pox.....	12	
Dysentery.....	1	Unclassified.
Fish poisoning.....	1	
Malaria.....	1	Malignant tertian.
Syphills.....	4	2 imported; 2 primary.
In St. Croix:		
Chicken pox.....	5	
Dysentery.....	1	Entamebic.
Erysipelas.....	1	
Filariasis.....	8	Bancrofti.
Gonococcus.....	3	
Leprosy.....	1	
Syphills.....	5	Secondary.
Trachoma.....	4	
Tuberculosis.....	1	Chronic pulmonary.
Uncinariasis.....	1	Necator americanus.
