INDICES OF NUTRITION.

THE APPLICATION OF CERTAIN STANDARDS OF NUTRITION TO 506 NATIVE WHITE CHILDREN WITHOUT PHYSICAL DEFECTS AND WITH "GOOD" OR "EXCELLENT" NUTRITION AS JUDGED FROM CLINICAL EVIDENCE.¹

By TALIAFERRO CLARK, Surgeon; EDGAR SYDENSTRICKER, Statistician; and SELWYN D. COLLINS, Assistant Statistician, United States Public Health Service.

The search for a practicable and dependable, yet simple, index of physical fitness has been given much emphasis in the last few years. The desire for such an index is a natural one, and the need for it is felt to an increasing degree. As greater attention is being given to the supervision of large groups of persons, such as school children and industrial employees, and greater interest is being taken by the individual in his own health, the advantages of some easy but fairly accurate method of determining whether or not an individual is in good health are more widely recognized and urged.

The search has been conducted in more than one direction, and several kinds of indices of physical fitness have been proposed. Some have already been used widely and others are being suggested and discussed. The demand for an adequate index is now so widespread and the need for it so obvious that attempts are being made to establish some sort of uniformity in the various indices already in use, especially for children, by securing agreement among students of the question and among those who use indices of physical fitness in health administrative work. As a contribution to the scientific as well as to the practical phases of the question, a comparative study of several of the more widely known methods of assessing physical fitness has suggested itself to the writers in the course of their inquiries. The present paper, therefore, is an attempt to make such a comparison from the point of view of actual results of applying different indices to a single group of children. The comparison is, in a sense, a test of the practical application of these methods, and the results here presented constitute another stage in a series of

¹ From Field Investigations in Child Hygiene, United States Public Health Service, in cooperation with the Statistical Office, United States Public Health Service. This is the third article in a series on weight and height of school children.

studies conducted by the Child Hygiene and Statistical Offices of the United States Public Health Service.

Before entering into a description of the method of the present study and the presentation of its results, a brief orientation in the general situation regarding the scope, use, and nature of the various indices now employed or proposed seems pertinent.

It appears fairly well recognized, at least by those who are not over-enthusiastic over some particular method, that the proper function of an index of physical fitness must be within well-defined limits. So far as its use can be defined at present, an index of this nature can not be expected to do more than to tell accurately whether or not the individual's condition of health is satisfactory; it can not, in cases where an unsatisfactory condition of health exists, be expected to diagnose the cause. It may in some cases suggest the nature of the cause, provided the index itself takes into account certain specific conditions which are at the same time well-recognized symptoms of more or less specific complaints, defects, or diseases. But, generally speaking, the most that can be hoped for in an efficient index of physical fitness is nothing more than a means of separating the physically well in a group of persons, such as school children or industrial employees, from those who are not well or who probably are not well. Those who are left in the latter category must be more carefully examined by medically trained inspectors and kept under observation for such treatment or supervision as may be advisable. Moreover, to go a step further, it should be expected of such an index that it can be applied by persons of average intelligence and some elementary training in hygiene, but not necessarily with medical training, to separate the children in good health from those in need of attention, and thus permit of frequently repeated wholesale health inspections at reasonable expense. Finally, it is greatly desired that an index of this kind should be capable of numerical expression for purposes of accuracy, ease in use, and greater applicability and appeal in health administration.

With this general objective in mind, the search for an index of physical fitness may be said to have been conducted so far chiefly along three lines which, briefly, may be summarized as follows:

(1) To grade the subject according to several more or less well-defined and well-recognized signs of health. The first definite product of the search in this direction was the now well-known Dunfermline scale. While some modifications of the Dunfermline scale have been suggested, no considerable further progress has been made in developing a scale which, by empirical methods, might give proper values to various easily observed indications of ill-health or of health, and make possible a system of grading that, after repeated tests upon different classes and groups of individuals,

would afford a practicable and accurate index. It safely may be ventured that the possibilities of developing an index along these lines have not been fully explored.

(2) To use the variation in a *single* physical characteristic as a measure of physical fitness. The specific characteristic which has been almost exclusively employed is *weight*. First applied (in the sense of increment of weight) for judging the development and health of infants, it was next applied to adults and children, although differently. Since it was soon found that normal children differed in weight according to sex and age, the attempt was made to take into account these two variables. More recently it has been urged that children, as well as adults, differ normally with respect to "type of build," and an attempt has been made to set up "standard" or "normal" weights of children of different "types of build," and of different sexes and ages. In fact, even further refinements are being suggested. Since any such "standard" or "normal" weight is, of necessity, an average unless refinements are carried to an impossible degree, the further suggestion is made that a certain amount of deviation from the average should be allowed to take care of variations that do not indicate ill health, but which actually occur among healthy individuals. Obviously, if a suggestion of this sort is to be carried out in a scientific manner, it is equally as important to determine the limits of this "zone," as it has been termed, of normal variability from a given average as it is to determine the average itself. Our own studies have suggested quite clearly that even for healthy children the variability in weight differs in a marked degree according to sex and age, and it would appear necessary to delimit normal variation for each sex, age, and other groups. So far, the suggestions as to the limits of these zones appear to have been based upon opinion rather than upon investigation, and do not take into account the variables mentioned.

(3) To employ the variations in more than one physical characteristic, such as weight, sitting height (stem-length), chest circumference and vital (lung) capacity, either (a) in relation to each other for the purpose of establishing an index of build, for example, or (b) in some combination, as an index of physical fitness. Of the last named, the method proposed by Dreyer² is at present the most elaborate. The possibilities in this direction would appear to be numerous and suggestive.

In a sense, some of the indices offered embody more than one of the principles suggested in the foregoing. For example, in Taylor's³ idea of taking "type of build" into consideration, children would

² Georges Dreyer and George F. Hanson: *The Assessment of Physical Fitness*. Cassell & Co., Ltd., London, 1920.

³ Charles K. Taylor: *Physical Standards for Boys and Girls*. The Academy Press, Orange, N. J., 1922.

first be classified according to type of build and then judged according to their deviation from the specific average or normal zone of variation set up for that type of build. Again, before applying standard weight as calculated from vital capacity, Dreyer would classify the individual according to some characteristic, such as activity, occupation, etc. Without entering at this time into a discussion of the principles involved, it may be mentioned that the obvious objection to such a procedure is that any conclusion based on numerical deviations (unless the deviations are extraordinary, in which case the need for any index is doubtful) from an average is likely to be misleading when the subject has been previously classified according to the observer's impression or according to so vague a distinction as occupation.

This paper is not concerned with indices of physical fitness, based on laboratory examination of blood, excreta, etc., reactions to various stimuli, and the like.

In the present study, three well-known indices of nutrition in which *weight* is the physical characteristic primarily employed as the measure of health or, conversely, of deviations from health have been selected for test and comparison. In general, the procedure was as follows: (1) To select children who, upon a detailed physical examination by experienced medical men, were found to be without defect or evidence of disease, as the basic or experimental (from the statistical point of view) group; (2) to apply each of the three indices to the individuals within this group; (3) to compare the results of the application of the three indices, in order to ascertain how far they agree. In the selection of the basic group of children, a further limitation was introduced, namely, all children who, even without physical defect or evidence of disease, were graded upon the basis of clinical evidence as "fair," "poor," and "very poor" in nutrition were excluded. Since two classes of gradation according to nutrition ("good" and "excellent") were included, the results of the study suggest in some degree the applicability of a modified Dunfermline scale. It was assumed, at the beginning of this study, that any satisfactory standard of physical fitness should work in two ways: it should include all or very nearly all of a group of children who, judged by the best standard available (a careful examination by qualified medical inspectors experienced in this particular work), are found beyond reasonable question to be in a satisfactory, if not superior, condition of health; and, conversely, it should not include any large proportion of a group which, by the same method, is found to be in ill health. The principle of the test would appear to be more than fair, since all "border-line" cases are excluded from consideration.

The present study deals only with the first application of the test outlined above, namely, the ability of selected standards to include within their limits of normality children who, on medical examination, have been found free from defect and in satisfactory physical condition. The other application is reserved for further study.

I. STANDARDS OF NUTRITION SELECTED.

For the purpose of this study, three standards were selected for examination and comparison, as follows:

1. The first standard considered is that devised by Dr. Thomas D. Wood.⁴ This standard is too well known and too widely used in school health work in the United States to require much explanation here. It consists of average weights of children of each sex, by age and standing height. In the application of this standard, a variation of 10 per cent below the average is usually classed as normal, but anything under this point is said to indicate malnutrition.

2. The second standard considered in this study is one devised by Georges Dreyer.⁵ According to this standard, a person of a certain trunk length (sitting height) should weigh a certain amount. Similarly a person of a certain chest circumference (at rest) should weigh a certain amount. To determine the normal weight of a given individual, average the weights for the trunk length and for the chest circumference of that person as given in Dreyer's tables. Age is not considered, the tables being prepared for males and females to apply to any age.⁶ According to Dreyer, the following scale classifies persons as to underweight:

Deviation of 5 to 10 per cent, possibly abnormal.

Deviation of 10 to 15 per cent, probably abnormal.

Deviation of 15 per cent or more, certainly abnormal.

3. The third standard for comparison is that of Pirquet,⁷ according to which the cube root of ten times the weight in grams divided

⁴ Right Height and Weight for Boys and Girls. Prepared by Dr. Thomas D. Wood.

⁵ See footnote 2, p. 1241.

⁶ The method described above as Dreyer's standard applies only to *weight*; that is, the tables so used are to indicate whether the weight is normal. Dreyer also has a standard of *physical fitness* which is based on vital capacity in relation to weight, trunk length (sitting height), and chest circumference at rest. Tables are given to show the normal vital capacity for persons of different trunk lengths and chest circumferences. Tables are also given to show the normal vital capacities for each weight. If the person is of normal weight, reference is made to the latter tables to find his normal vital capacity. If, however, the person is above or below normal weight, the procedure specified is to look up the vital capacity corresponding to the trunk length of the given individual and the vital capacity corresponding to the chest circumference. These two are averaged to find the normal vital capacity.

For the purpose of vital capacity norms, persons are classified into classes A, B, and C; class A having the highest vital capacity and class C the lowest. Athletes and other active persons are put in class A, whereas clerks are put in class C. However, the classification does not seem to be made purely on the basis of activity. But Dreyer indicates that elementary school children belong in class C.

The application of this standard of physical fitness was not attempted at this time, owing to the absence of necessary data which is now being assembled and will be presented in a future study.

⁷ An outline of the Pirquet System of Nutrition. By Clemens Pirquet. W. B. Saunders, Philadelphia and London, 1922.

by the sitting height in centimeters should equal 100 in a normal child. To put it in the form of an equation:

$$\frac{\sqrt{10} \times \text{Weight in grams}}{\text{Sitting height in centimeters}} = 100$$

The resulting figures (100 in normal persons) are called "pelidisi," a word coined by Pirquet to denote the nutritional status of individuals. To work out this formula for each child would become laborious, but tables have been prepared showing the pelidisi for each centimeter of sitting height and each weight.⁸ Sex and age are not considered, the table applying to either sex of any age.⁹

	Sanguis (blood).	Crassi- tudo (fat).	Turgor (water).	Mus- cu- laris (mus- cle).	
i	Si	cri	ti	mi	Greatly increased.
e	Se	cre	te	me	Moderately increased.
a	Sa	cra	ta	ma	Normal.
o	So	cro	to	mo	Moderately decreased.
u	Su	cru	tu	mu	Greatly decreased.

II. APPLICATION OF STANDARDS TO INDIVIDUAL CHILDREN.

The children used in this study were selected from a large group of children after physical examination. The physical examination and nutrition classification were made by medical officers of the United States Public Health Service. Certain special physical measurements were made of selected children who were free from physical defects and in good health. The special measurements comprised the taking of the standing height, sitting height, weight, chest circumference, and certain other measurements not considered in this study. The children were measured in all cases without shoes and dressed only in light indoor clothing or underclothes. At the same time the nutrition of the child, as judged from clinical evidence, was set down by the examining medical officer as "excellent," "good," "fair," "poor," or "very poor."

In order to eliminate the personal equation of individual examiners, certain precise instructions were prepared for their guidance. The instructions for grading nutrition were as follows:

Check the child's nutrition as excellent, good, fair, poor, or very poor. This should be done after the outer clothing has been removed and without reference to existing standards of height and weight. Judge nutrition by general appearance, activity,

⁸ The table for determining pelidisi used in this study is that given by William E. Carter in an article on "The Pirquet System of Nutrition and Its Applicability to American Conditions," which appeared in the Journal of the American Medical Association, Vol. 77, No. 20, pp. 1541-46 (November 12, 1921). After the appearance of Pirquet's book this table was compared with the one given by him. The two tables agreed, except for a few obviously typographical errors and slight differences which did not in any way affect the results of this study.

⁹ In order to supplement the pelidisi table, Pirquet standardized the method of physical examination of the child and classified the results under four headings: Sanguis, Crassitudo, Turgor, and Muscularis. He used the vowels, *a* to indicate normality, and *e*, *i*, *o*, *u* to designate the degree of deviation of these tissues from the normal. In this way there was evolved the word "Sacratama" to denote the physical examination according to the following table:

condition of the skin, amount of subcutaneous fat, muscle tone, alertness, and vitality of the child.

For the purpose of comparing different standards of nutrition, children were selected for this study on the following basis:

1. Native-born white children.
2. Both parents and all four grandparents born in the United States.
3. Recorded as appearing normal.
4. Have no physical defects.
5. Nutrition "good" or "excellent" as judged from clinical evidence.

The group of children satisfying these requirements were then divided into two classes according to the state of nutrition, one group comprising the children whose nutrition as judged from clinical evidence was recorded as "excellent," and the other group composed of those whose nutrition was recorded as "good." As explained above, the children were classified into five nutrition groups: "excellent," "good," "fair," "poor," and "very poor." The "excellent" group is, therefore, made up of children whose nutrition was beyond question. The "good" group represents children whose nutrition was above the average and could be said to be at least satisfactory.

In other words, so far as could be judged from a single examination, the children selected included no "border-line" cases, since they were definitely satisfactory so far as clinical evidence of nutrition was concerned, and clearly with no evidence of ill health. The objection may possibly be raised that if they had been kept under observation for a reasonable period, some of them might have been found to show signs of ill health which a single examination would fail to disclose. Within narrow limits, the objection, theoretically, at least, is a valid one, but experienced clinicians would hardly consider it an invalidating one. It is only proper to state, however, that material is being collected, in the course of further studies, which will include children who have been under observation for considerable periods.

The 506 children whose measurements were used as the basis for this study were from four States. The following table shows the distribution of the children according to the State in which they resided.

TABLE I.—*Distribution according to sex and place of residence of 506 children whose measurements were used as the basis for this study.*

Native white children of native parentage and native grandparentage with no physical defects and with "good" or "excellent" nutrition as judged from clinical evidence.

State of residence.	Both sexes	Boys	Girls
All States.....	506	227	279
Florida.....	130	58	72
Georgia.....	159	80	79
Tennessee.....	110	46	64
Utah.....	107	43	64

Although the children lived in different States, they were all of not less than third generation native white children. Moreover, the distributions of the children according to underweight and overweight by the different standards used were similar in the various States (see Appendix, Tables XII, XIII, and XIV). Therefore, it seemed reasonable to combine the four States for the purpose of this study.

Table II shows the distribution of the 506 selected children according to age, sex, and nutrition.

TABLE II.—*Distribution according to sex, age, and nutrition of the 506 children whose measurements were used as the basis for this study.*

Native white children of native parentage and native grandparentage with no physical defects and with "good" or "excellent" nutrition as judged from clinical evidence.

WOOD'S STANDARD.

According to Wood's standard, based on the weight for height at different age periods for each sex, 102, or 20 per cent, of these 506 children found in good health and free from physical defect on medical examination, were more than 10 per cent underweight. According to this standard there was slightly more underweight among the girls than among boys, 21 per cent of the girls being underweight as against 19 per cent of the boys.

It is of more than passing interest to note that this finding of 20 per cent of *healthy* children who appear to be underweight according to Wood's standard is not so very much different from the results obtained by the application of this standard in a number of extensive studies on *unselected* children attending school. It will be recalled that these results were rather generally interpreted as revealing a definitely unsatisfactory condition of health.

TABLE III.—*Wood's "right" weight applied to children without physical defects and with "good" or "excellent" nutrition as judged from clinical evidence.*

Percentage of 506 children of native white ancestry (parents and grandparents all born in the United States) who were more than 10 per cent underweight, and percentage who were more than 20 per cent overweight according to Wood's height-weight-age tables, by sex and age groups.

Age, nearest birthday.	Percentage of children—						Total number of children considered.		
	Underweight (more than 10 per cent under Wood's standard).			Overweight (more than 20 per cent over Wood's standard).					
	Both sexes.	Boys.	Girls.	Both sexes.	Boys.	Girls.	Both sexes.	Boys.	Girls.
All ages.....	20.2	18.9	21.1	4.3	4.4	4.3	506	227	279
6-8.....	17.7	23.3	14.3	1.3	3.3	-----	79	30	49
9-11.....	21.7	17.7	24.8	5.6	3.8	6.9	180	79	101
12-14.....	20.0	16.7	22.9	4.9	5.2	4.6	205	96	109
15-18.....	19.1	27.3	10.0	2.4	4.5	-----	42	22	20

TABLE IV.—*Wood's "right" weight applied to children without physical defects and with "good" or "excellent" nutrition as judged from clinical evidence.*

Percentage of 506 children of native white ancestry (parents and grandparents all born in the United States) who were more than 10 per cent underweight and percentage who were more than 20 per cent overweight according to Wood's height-weight-age tables, by sex and nutrition groups.

Nutrition as judged from clinical evidence.	Percentage of children—						Total number of children considered.		
	Underweight (more than 10 per cent under Wood's standard).			Overweight (more than 20 per cent over Wood's standard).					
	Both sexes.	Boys.	Girls.	Both sexes.	Boys.	Girls.	Both sexes.	Boys.	Girls.
Both nutrition groups.....	20.2	18.9	21.1	4.3	4.4	4.3	506	227	279
Excellent.....	4.1	6.6	2.3	12.8	13.1	12.6	148	61	87
Good.....	26.8	23.5	29.7	.8	1.2	.5	358	166	192

When the children are classified according to age there are too few individuals in the groups, especially when further classified according to sex, to justify any conclusions from these data as to variation in the percentage of underweight at different ages.

Comparing the children of "good" with those of "excellent" nutrition, as judged from clinical evidence (Table IV), 4 per cent of the "excellent" group were more than 10 per cent under Wood's standard, as against 27 per cent of the "good." Among the boys the corresponding percentages were 7 per cent for the "excellent" and 23 per cent for the "good"; among girls 2 per cent of the "excellent" were underweight and 30 per cent of the "good."

In the matter of overweight no very common standard has been established, but a variation of 20 per cent above Wood's table has been used to a considerable extent as an indication of overweight. In this study, children over 20 per cent above Wood's standard were tabulated as overweight. In the "excellent" group 13 per cent of the children were more than 20 per cent above Wood's standard, whereas less than 1 per cent were overweight in the "good" group.

Two things seem clear from these data; first, that all the fat children were classed as "excellent" in nutrition; and second that nutrition as judged from clinical evidence was, to a degree, influenced by weight in relation to height; that is, there is direct correlation between underweight and nutrition. However, according to Wood's standard, 4 per cent of children without physical defects and of "excellent" nutrition, as judged from clinical evidence, were found to be underweight, and 27 per cent of those of "good" nutrition. This does not seem to be a sufficiently high correlation for weight to serve as a standard of nutrition.

DREYER'S STANDARD.

Out of the 506 children, 13 per cent (65 children) were more than 10 per cent below Dreyer's standard based on sitting height and chest circumference. Girls and boys, however, showed wide differences, only 2 per cent of the boys being underweight as against 22 per cent of the girls. When the children are divided into age groups it is found that for girls 6 to 8 years old the percentage who were underweight does not differ significantly from that of boys of the same age group, 7 per cent of the boys being underweight and 4 per cent of the girls. Reference to the more detailed tables in the appendix (Tables XVIII, XIX, and XX) will show that the difference between boys and girls shows up at about 10 years of age. Among boys 9 years and under, 4 per cent are underweight as against 3 per cent of the girls of the same age group.

In the other age groups, however, few boys are underweight, but 16 per cent of girls are underweight in the 9-11 year group, 36 per cent in the 12-14 year group, and 20 per cent in the 15-18 year group. The number of girls in each case is small but the differences between boys and girls are so large and consistent that some significant factor must have come in to cause the differences at these ages.

TABLE V.—Dreyer's "normal" weight applied to children without physical defects and with "good" or "excellent" nutrition as judged from clinical evidence.

Percentage of 506 children of native white ancestry (parents and grandparents all born in the United States) who were more than 10 per cent underweight, and percentage who were more than 15 per cent overweight according to Dreyer's tables of "normal" weight as calculated from trunk length and chest circumference, by sex and age groups.

Age nearest birthday.	Percentage of children—						Total number of children considered.		
	Underweight (more than 10 per cent under Dreyer's standard).			Overweight (more than 15 per cent over Dreyer's standard).					
	Both sexes.	Boys.	Girls.	Both sexes.	Boys.	Girls.	Both sexes.	Boys.	Girls.
All ages.....	12.8	1.8	21.9	10.0	17.6	3.6	506	227	279
6-8.....	5.1	6.7	4.1	11.4	16.7	8.1	79	30	49
9-11.....	8.9	15.8	7.2	11.4	4.0	180	79	101
12-14.....	20.0	2.1	35.8	11.2	21.9	1.8	205	96	109
15-18.....	9.5	20.0	11.9	22.7	42	22	20

The instructions for making the measurements on the children included in this study, for the application of Dreyer's method were taken almost verbatim from Dreyer's book, and specified that chest measurements of girls old enough for the breast to be developed should be taken under the breasts. The data suggest, however, that the chest measurements of girls have in some way caused the error either in the data presented in this article or in Dreyer's original computations, since few of the boys of any age and few of the girls under 10 years are underweight according to the Dreyer method. With this exception, which is being made the subject of further study, the Dreyer method of taking into account two measurements (in this instance the important ones of stem length and chest circumference) seems to yield better results than a single measurement, such as the standing height.

TABLE VI.—Dreyer's "normal" weight applied to children without physical defects and with "good" or "excellent" nutrition as judged from clinical evidence.

Percentage of 503 children of native white ancestry (parents and grandparents all born in the United States) who were more than 10 per cent underweight and percentage who were more than 15 per cent overweight, according to Dreyer's tables of "normal" weight, as calculated from trunk length and chest circumference, by sex and nutrition groups.

Nutrition as judged from clinical evidence.	Percentage of children—						Total number of children considered.		
	Underweight (more than 10 per cent under Dreyer's standard).			Overweight (more than 15 per cent over Dreyer's standard).					
	Both sexes.	Boys.	Girls.	Both sexes.	Boys.	Girls.	Both sexes.	Boys.	Girls.
Both nutrition groups.....	12.8	1.8	21.9	10.0	17.6	3.6	506	227	279
Excellent.....	13.5	1.6	21.8	10.8	21.3	3.4	148	61	87
Good.....	12.6	1.8	21.9	9.5	16.3	3.6	358	166	192

When the two nutrition groups as judged from clinical evidence are compared, the percentages underweight are almost the same, 13 per cent of the "excellent" and over 12 per cent of the "good." Similarly, overweight does not show a very large difference, less than 11 per cent of the "excellent" being more than 15 per cent overweight and more than 9 per cent of the "good." When boys and girls are considered separately, the percentages who are underweight are not significantly different in the two nutrition groups.

PIRQUET'S STANDARD.

According to the Pirquet "pelidisi" standard, 17 per cent of the children were underweight, having pelidisi of 94 or less; 13 per cent of the boys and 21 per cent of the girls were underweight.

TABLE VII.—*Pirquet's "pelidisi" method applied to children without physical defects and with "good" or "excellent" nutrition as judged from clinical evidence.*

Percentage of 503 children of native white ancestry (parents and grandparents all born in the United States) whose "pelidisi" was 94 or less and percentage whose "pelidisi" was 105 or greater, by sex and age groups.

Age nearest birthday.	Percentage of children—						Total number of children considered.		
	Underweight (pelidisi 94 or less).			Overweight (pelidisi 105 or more).					
	Both sexes.	Boys.	Girls.	Both sexes.	Boys.	Girls.	Both sexes.	Boys.	Girls.
All ages.....	17.2	12.8	20.8	16.6	17.2	16.1	506	227	279
6-8.....	26.6	23.3	28.6	8.9	10.0	8.2	79	30	49
9-11.....	21.7	13.9	27.7	11.1	8.9	12.9	180	79	101
12-14.....	12.7	11.5	13.8	21.0	22.9	19.3	205	96	109
15-18.....	2.4	5.0	33.3	31.8	35.0	42	22	20

When the children were divided according to age (Table VII), there was a fairly clear tendency in each sex group for the prevalence of underweight to decrease with age and the prevalence of overweight to increase with age. In the group composed of both sexes, the percentage underweight decreases from 27 per cent among children 6 to 8 years of age to 2 per cent among children 15 to 18 years of age. The percentage overweight increases from 9 per cent in the 6-8 year group to 33 per cent in the 15-18 year group. Although the numbers of children in these groups are small, the tendency described above seems fairly clear and consistent. It does not appear that the "pelidisi" method even approaches the degree of accuracy afforded by a physical examination. The results are even more unsatisfactory for younger children than for adults.

TABLE VIII.—*Pirquet's "pelidisi" method applied to children without physical defects and with "good" or "excellent" nutrition as judged from clinical evidence.*

Percentage of 503 children of native white ancestry (parents and grandparents all born in the United States) whose "pelidisi" was 94 or less and percentage whose "pelidisi" was 105 or greater, by sex and nutrition groups.

Nutrition as judged from clinical evidence.	Percentage of children—						Total number of children considered.		
	Underweight (pelidisi 94 or less).			Overweight (pelidisi 105 or more).					
	Both sexes.	Boys.	Girls.	Both sexes.	Boys.	Girls.	Both sexes.	Boys.	Girls.
Both nutrition groups.....	17.2	12.8	20.8	16.6	17.2	16.1	506	227	279
Excellent.....	10.8	9.8	11.5	17.6	24.6	12.7	148	61	87
Good.....	19.8	13.9	25.0	16.2	14.5	17.7	358	166	192

Comparing the children of "good" nutrition with those of "excellent" nutrition, as judged from clinical evidence, 20 per cent of the "good" were underweight as against 11 per cent of the "excellent."

In regard to overweight, 16 per cent of the "good" group were overweight as against 18 per cent of the "excellent."

In general, underweight, according to Pirquet's pelidisi method, showed correlation with nutrition as judged from clinical evidence, but it must be remembered that 11 per cent of the 148 children of "excellent" nutrition with no physical defects were underweight according to the Pirquet standard.

III. Comparison of the Different Standards.

The previous tables and discussion have shown the percentage of this selected group of healthy children who were underweight according to each of the three standards used. Of the 506 children, 102, or 20 per cent, were more than 10 per cent below Wood's standard; 65, or 13 per cent, were more than 10 per cent below Dreyer's standard; and 87, or 17 per cent, were underweight (pelidisi 94 or less), according to the Pirquet standard. The question arises as to whether the 102 children who were underweight according to the Wood table include the 65 and the 87 who were underweight according to the other standards. That is, how far do the standards agree on individual children?

A comparison is made in Table IX.

TABLE IX.—Comparison of indices of nutrition.

503 children of native white ancestry (parents and grandparents all born in the United States) without physical defects and judged as "excellent" or "good" in nutrition on clinical evidence by medical examiners (U. S. P. H. S.), the children being classified according to (1) Pirquet's "pellidisi" method, (2) per cent deviation from Wood's table of "right" weight for the sex, age, and height, and (3) per cent deviation from Dreyer's table of "normal" weight as calculated from trunk length and chest circumference.

BOYS.

GTR 8

Of 102 children who were more than 10 per cent underweight according to Wood, only 23 per cent (23 children) were underweight according to Dreyer, and 35 per cent (36 children) were underweight according to Pirquet. Of these 102 children underweight according to Wood, 5 per cent (5 children) were more than 15 per cent *overweight* according to Dreyer and 14 per cent (14 children) were *overweight* according to Pirquet (pelidisi 105 or over).

Of the 65 children who were more than 10 per cent below Dreyer's standard, 35 per cent (23 children) were underweight according to Wood, and 38 per cent (25 children) were underweight according to Pirquet.

Of the 87 children underweight according to Pirquet, 28 per cent (25 children) were underweight according to Dreyer and 41 per cent (36 children) were underweight according to Wood.

Of the 506 children, 210 were classed as underweight by one or more of the three standards; of these 210 cases, all three standards agreed on but 15 cases as being underweight.

The above figures are sufficient to show the great differences in the results of applying to healthy children the three methods of judging deviation from normal weight. Table IX shows the matter in greater detail.

The discussion thus far has considered the 506 children in one group. It will be remembered, however, that these children were classified by the medical officers who made the examinations according to nutrition as judged from clinical evidence without reference to any normal weight tables. Tables X and XI show cross tabulations similar to Table IX for the children of "good" nutrition and for those of "excellent" nutrition separately.

TABLE X.—Comparison of indices of nutrition.

358 children of native white ancestry (parents and grandparents all born in the United States) without physical defects and judged as "good" in nutrition, on clinical evidence, by medical examiners (U. S. P. H. S.), the children being classified according to (1) Pirquet's "pedilisi" method, (2) per cent deviation from Woods's table of "right" weight for the sex, age, and height, and (3) per cent deviation from Dreyer's table of "normal" weight as calculated from trunk length and chest circumference.

TABLE XI.—Comparison of indices of nutrition.

148 children of native white ancestry (parents and grandparents all born in the United States) without physical defects and judged as "excellent" in nutrition, on clinical evidence by medical examiners (U. S. P. H. S.), the children being classified according to (1) Pirquet's "pelidisi" method, (2) per cent deviation from Wood's table of "right" weight for the sex, age, and height, and (3) per cent deviation from Dreyer's table of "normal" weight as calculated from trunk length and chest circumference.

TABLE XI.—*Comparison of indices of nutrition*—Continued.
EXCELLENT NUTRITION—Continued.

IV. Summary.

1. For the purpose of comparing different indices of nutrition, a group of 506 children who had the following qualifications were selected from much larger numbers: (a) Native white of native parentage and native grandparents; (b) no physical defects; and (c) nutrition "good" or "excellent" as judged from clinical evidence.

These children were selected after careful physical examination as being in good health so far as the medical examiner (United States Public Health Service) could determine.

2. Three standards of weight were applied to them. It was found that according to the Wood standard (height-weight-age tables), 20 per cent of these children were more than 10 per cent underweight; according to Dreyer's standard (stem length and chest circumference tables), 13 per cent of the children were more than 10 per cent underweight; and according to Pirquet's "pelidisi" method, 17 per cent had pelidisi of 94 or less and were underweight according to this standard.

3. A cross tabulation was made to ascertain whether children underweight according to one standard were underweight according to other standards. Although the percentage of children who were underweight did not vary greatly when different standards were applied (13, 17, and 20 per cent), many individuals classed as underweight by one standard were classed as normal or, in a few cases, overweight, by one or both of the other standards. Out of 506 children, 210 were classed as underweight by one or more of the three standards used; of these 210 cases, all three standards agreed on 15 cases as being underweight.

These children were selected as the best specimens of health that could be found among school children. In spite of this fact, one-fifth of them were underweight according to the standard most frequently used in school health work in the United States.

Appendix.

The following tables show in greater detail the data which have been presented in summary form in the foregoing pages:

TABLE XII.—*Distribution of children in different States according to deviation from standard weight.*

Frequency distribution of 506 children of "good" or "excellent" nutrition as judged from clinical evidence, according to the percentage deviation from Wood's "right" weight for sex, age, and height, according to the percentage deviation from Dreyer's "normal" weight for trunk length and chest circumference, and according to Pirquet's "pelidisi" standard, by sex and State of residence.

BODY WEIGHT AND LONGEVITY.

Whether or not the weight-height ratio is a reliable index to the state of nutrition or health in children, it would seem that the mortality experience of insurance companies indicates definitely that overweight at certain ages involves serious danger to the lives of their policyholders, the degree of danger increasing with the excess in weight over the average for height and age for certain ages. At younger ages, however, a limited amount of overweight appears to be of advantage, or associated with more favorable mortality conditions, overweight persons of such ages having a uniformly lower death rate from tuberculosis. The records indicate that after 35 years of age, overweight, even in relatively small amounts begins to be dangerous, the seriousness increasing with advancing age and amount of overweight. The following statements, based on the records of insurance companies,¹ are taken from the Statistical Bulletin of the Metropolitan Life Insurance Co. for November, 1922:

Among short men—that is, those below 5 feet 7 inches in height—at the age period 40 to 44 years, an excess of 20 per cent in weight involves an added mortality of 30 per cent above the normal. A 40 per cent excess in weight in such individuals involves an increased mortality of nearly 80 per cent. Among tall men—that is, those over 5 feet 10 inches in height—the adverse situation is even more marked; for among them, at ages 40 to 44, a 20 per cent excess in weight carries a 40 per cent increase in mortality, and a 40 per cent excess in weight doubles the mortality.

On the other hand, underweight, which is common enough, presents a different picture. In general, underweight is an advantage, provided, of course, the percentage of deficiency is not too great. It is a serious impairment in early adult life, especially among tall men. Persons who are over 5 feet 10 inches and who are 20 per cent below the average weight for their height show an increased mortality of 30 per cent. Persons 30 per cent underweight have a 50 per cent excess mortality at these early ages. But from age 40 onward there are apparently no such penalties for underweight, and this condition, in fact, becomes a distinct advantage; for these are the people who have the best mortality rates.

It would seem that the records of insurance companies indicate that there is an optimum weight—that is, a weight-height ratio in relation to age that is associated with the most favorable mortality experience, and that this optimum weight, or best build, is not the average build. It is stated that those who weigh between 10 and 20

¹ Report of the Joint Committee of the Actuarial Society of America and the Association of Life Insurance Medical Directors, New York, 1918.

per cent below the average show the optimum condition for longevity at most ages beyond early adult life.

Continuing the question of optimum weight, or best build, as indicated by insurance records, it is stated in the Statistical Bulletin for March, 1923, that at ages under 30 years the lowest mortality rates among insured persons are found in those whose weights are above the average, an excess of weight of about 10 pounds above the average producing the most favorable mortality rates between the ages of 20 and 24 years. This excess tapers off until about age 30, at which age the lowest mortality is found among persons of approximately average weight. Beyond age 30, the lowest mortality is found among persons whose weights are below average, the amount of underweight associated with the most favorable mortality increasing with advancing age. At age 50 optimum weight appears to be, on the average, 30 to 40 pounds below the average weight for that age.

Discrimination must be made between types of build of overweight persons, it being shown that among overweights having a large chest capacity the conditions of mortality are more favorable than among those of small chest capacity. Overweights who have large trunks are better risks than those having small chests and large abdominal girth.

On the assumption that the average weight is the best weight, tables of average weights lead to the erroneous supposition that weight should continue to increase with advancing age. While this increase is of very common occurrence, the insurance records indicate that, within certain limits, this excess weight increases the insurance risk and should be carefully avoided.

These records, together with clinical evidence, suggest that through restriction of diet and proper indulgence in some form of exercise conditions premonitory of organic impairment and eventual breakdown of the circulatory and excretory systems may be averted in many instances. At least they reinforce what hygienists have been advocating for many years and open up a promising field of investigation for physiological research.

COMPENSATION FOR TYPHOID FEVER UNDER WORK-MEN'S COMPENSATION ACT.

Typhoid fever contracted by an employee of a hotel as the result of drinking impure well water furnished by the hotel has been held¹ compensable as an accident within the meaning of the workmen's compensation act by the Supreme Court of Michigan.

¹ Frankamp v. Fordney Hotel et al., 193 N. W. 204.

QUARANTINE FOR VENEREAL DISEASES UPHELD.

The commissioner of health of Akron, Ohio, placed two venereally infected women under quarantine pursuant to authority contained in regulations adopted by the public health council of the State department of health. In habeas corpus proceedings¹ brought by the two women, the Supreme Court of Ohio held the regulations not to be violative of either the Federal or State Constitution, but held them to be a proper exercise of the police power of the State.

^c Deaths for week ended Friday May 25, 1923.

PREVALENCE OF DISEASE.

No health department, State or local, can effectively prevent or control disease without knowledge of when, where, and under what conditions cases are occurring.

UNITED STATES.

CURRENT STATE SUMMARIES.

These reports are preliminary, and the figures are subject to change when later returns are received by the State health officers.

Reports for Week Ended June 2, 1923.

TUBERCULOSIS.

See p. 1285; also Current State summaries, p. 1275.

CITY REPORTS FOR WEEK ENDED MAY 19, 1923—Continued.

TYPHOID FEVER.

The column headed "Median for previous years" gives the median number of cases reported during the corresponding week of the years 1915 to 1922, inclusive. In instances in which data for the full eight years are incomplete, the median is that for the number of years for which information is available.

City.	Median for pre- vious years.	Week ended May 19, 1923.		City.	Median for pre- vious years.	Week ended May 19, 1923.

FOREIGN AND INSULAR.

BRAZIL.

Further Relative to Dengue Fever—Rio de Janeiro.¹

Under date of April 6, 1923, an outbreak of dengue fever was reported at Rio de Janeiro, Brazil. Information dated April 27 shows an increase in the number of cases in the district and city reported during the preceding 10 days, the increase being particularly in the city. No mortality was reported.

CANADA.

Lethargic Encephalitis—Winnipeg.¹

During the period April 1 to May 19, 1923, eight cases of lethargic encephalitis with two deaths were reported at Winnipeg, Manitoba, Canada.

CHILE.

Mortality—Concepcion—April, 1923.

During the month of April, 1923, 205 deaths were registered at Concepcion, Chile, including pneumonia, 52; smallpox, 4; tuberculosis, 16; typhoid fever, 2; typhus fever, 4. Population, officially estimated, 64,512.

CUBA.

Communicable Diseases—Habana.

Communicable diseases have been notified at Habana as follows:

Disease.	May 11-20, 1923.		Remaining under treatment May 20, 1923.
