PUBLIC HEALTH REPORTS

VOL. 44 FEBRUARY 1, 1929

NO. 5

INFLUENZA PREVALENCE IN THE UNITED STATES

Telegraphic reports from the health officers of 44 States for the week ended January 19, 1929 (see p. 248), show decreases in the number of cases of influenza in all sections of the United States except in New York and New England.

The total number of cases of influenza reported to the Public Health Service for the week was less than 90,000, which may be compared with 140,000 cases reported for the preceding week.

The department of health of the State of New York received reports of influenza from 227 localities in 55 counties of the State (outside of New York City) for the week ended January 19, 1929. These reports indicated a considerable increase over the reports for the preceding weeks. Many local health officers reported that the disease was mild.

SUMMARY OF INFLUENZA MORTALITY 1

Mortality from influenza and pneumonia during the current epidemic in a group of cities of the United States is shown in Table 1, with comparative data for the epidemics of 1918, 1920, and 1926.

Table 1.—A comparison of the weekly excess mortality rate (annual basis) per 100,000 for influenza and pneumonia during the influenza epidemics of 1918, 1920, 1926, and 1928, in the large cities of the United States

1918		1920		1926		1928-	-29
Week ended—	Excess •	Week ended—	Excess •	Week ended—	Excess b	Week ended—	Excess •
Sept. 14	-6 76 326 1, 028 2, 557 4, 992 4, 695 3, 332 1, 832 989 620 526 617 792 801 629	Jan. 17	-27 184 741 1, 241 1, 319 867 422 185 69 9	Feb. 6	-2 8 73 82 97 149 200 241 194 131 84 14 28 29	Nov. 17	-9 11 35 60 122 233 276 392 426 328

Excess over corresponding week of median year of the period 1910-1916 in cities included in the Weekly Health Index of the Bureau of the Census. Data from Public Health Reports, Mar. 26, 1920 (35:748).
 Excess over corresponding week of 1925 in 96 cities included in the Public Health Reports of the Public Hea

¹ From the Office of Statistical Investigations, U. S. Public Health Service.

For the group of cities as a whole the excess mortality from influenza and pneumonia reached a peak of 426 per 100,000 (annual basis) in the week ended January 12, 1929, and by January 19 had declined to 328 per 100,000, or considerably less than the excess rate of 392 for the week ended January 5, 1929.

The peak of the reported cases in the States reporting to the Public Health Service came in the week ended December 22, 1928, or three weeks earlier than the peak of the mortality. Some lag in the mortality would, of course, be expected.

Comparing the present outbreak with former epidemics of influenza that have occurred in recent years, it may be seen that in the peak week the mortality of the 1928–29 epidemic was nearly twice the mortality of the corresponding week of the 1926 epidemic. The excess mortality rate in the 1920 epidemic was about three times the present excess rate, and the 1918 epidemic showed a mortality in the peak week of more than ten times the peak mortality of the present outbreak.

Small but distinct epidemics occurring in the early months of 1922 and of 1923 are not shown in the table. They were of less importance in mortality than the 1926 epidemic. The outbreak of 1928–29 is, therefore, the most severe since 1920. Were it not for the overshadowing effect of the pandemic of 1918 and the 1920 epidemic, the present outbreak would probably be considered more seriously.

Data for the cities in each geographic division are shown in Table 2.

Table 2.—Excess mortality from influenza and pneumonia per 100,000 population in cities of the various geographic divisions of the United States

EXCESS: ANNUAL RATE PER 100.000

Considering the different geographic divisions, the mortality in the cities from which data are available is definitely on the decline in every division except in the New England, Middle Atlantic, and South

¹ Excess over the average of the years 1924-1927 up to Jan. 5 and excess over the average of the years 1924, 1925, and 1927 after that week. The data for 1924-1927 (not shown in this table) are based on cities reporting to the Public Health Service. For 1928 this is true for the geographical districts, except for the last few weeks, when the Weekly Health Index of the Census Bureau was used. Although the cities are not identical in the two cases, a test has shown that the effect on the rates is slight. For the "Total" line, the 1928 data were taken entirely from the Weekly Health Index.

Atlantic sections. The South Atlantic and Middle Atlantic cities appear to have about reached their peak, as the excess rate for the week ended January 19, 1929, is about the same as that for the preceding week. In New England, however, the rise in the week ended January 19 was considerable, but the excess mortality even in that week was relatively low.

On the Pacific coast the mortality was back to normal proportions on January 19, and the Mountain cities were only slightly above normal.

CURRENT WORLD PREVALENCE OF COMMUNICABLE DISEASES 1

The United States, December 2, 1928-January 5, 1929

The prevalence of certain important communicable diseases, as indicated by weekly telegraphic reports from State health departments ² to the Public Health Service, from December 2 to January 5, is summarized below.

Influenza.—Brief summaries of the influenza situation may be found on the preceding pages of this issue and in issues for preceding weeks in January and December.

Meningococcus meningitis.—Reports indicated an increase in the prevalence of meningococcus meningitis during the month of December considerably in excess of the normal increase for this season of the year. Nearly all of the States showed some increase in the number of cases, but the most significant increases were reported in North Dakota, Colorado, Oregon, California, Missouri, Montana, Kansas, and Connecticut. For the five weeks ended January 5, 1929, the cases totaled approximately 700, as against 295 cases for the corresponding period in 1927, and 185 cases in 1926.

Poliomyelitis.—The poliomyelitis rate continued to decrease during December, and for the week ended January 5, 1929, the lowest incidence of the disease (10 cases) was recorded since the week ended April 23, 1927, when only 8 cases were reported. Of the 10 cases reported, 5 occurred in New York State and the other 5 were widely scattered over the country. The rate for the five weeks ended January 5, however, was still considerably in excess of the rate in 1926 for the same period.

Smallpox.—In Illinois the cases of smallpox reported during the five weeks ended January 5, 1929, totaled 330, as against 125 for the preceding 5-week period; in Indiana the number of cases increased

¹ From the Office of Statistical Investigations, U. S. Public Health Service.

² The number of States reporting for the various diseases were as follows: Typhoid fever, 41; poliomyelitis, 43; meningococcus meningitis, 42; smallpox, 42; measles, 38; diphtheria, 42; scarlet fever, 41.

from 111 to 225; in Nebraska from 71 to 177; in Oklahoma from 97 to 160; in West Virginia from 33 to 105. The usual seasonal increase in prevalence was noted in other sections of the country, but the incidence continued considerably below that of the corresponding period in the years 1927 and 1926.

Diphtheria.—Reports from the East South Central and South Atlantic States showed marked decreases in the incidence of diphtheria in those sections of the country during the month of December. Slight increases were noted in some of the other States, but the general tendency was toward a decline in the prevalence of the disease. A slightly lower rate than in the corresponding period of either of the two preceding years was maintained during the five weeks ended January 5, 1929.

Typhoid fever.—During the month of December, the typhoid fever rate reached a level considerably lower than was recorded in the two preceding years for the corresponding month. For the five weeks ended January 5, 1929, the number of cases totaled 779—approximately 600 less than were reported in 1927, and 1,000 less than in 1926.

Measles.—The increase in measles which began in the New England and Middle Atlantic States during the month of November, spread through various sections of the country in December. For the five weeks ended January 5, 1929, the incidence rate was practically the same as was recorded during the same period in 1927, but was considerably less than that in 1926.

Scarlet fever.—The incidence of scarlet fever increased slightly during the month of December. However, for the five weeks ended January 5, 1929, the rate was approximately the same as in 1927, for the same period, and slightly below the rate for 1926.

Mortality from all causes.—The mortality from all causes in large cities experienced a very sudden rise early in the month of December, which can, without a doubt, be attributed to the outbreak of influenza that began late in October. The death rate increased steadily throughout the month, and for the week ended January 5, 1929, the rate for 65 large cities was 19.5 per thousand population. For the corresponding period in 1928 the rate was 13.7 and in 1927 it was 14.7.

The total death rate for 66 large cities for the year 1928 was 13, compared with 12.2 for 1927.

Foreign Countries 1

The prevalence of certain communicable diseases in most foreign countries during September, October, and part of November is summarized in the following pages.

¹ Data from the Monthly Epidemiological Report of the Health Section of the League of Nations' Secretariat, Nov. 15, 1928, supplemented by information published in the Public Health Reports.

"Marseilles exanthematic fever."—The "Marseilles exanthematic fever" is the name given to a disease observed since 1922 in Marseilles and Provence, with an apparently increasing incidence. It is possible that cases seem to be more numerous because the disease is more correctly diagnosed as it becomes better known. One case was observed in 1922, 2 cases were noted in 1923, 6 in 1924, 8 in 1925, 9 in 1926, and 38 in 1927. The number of cases observed in 1928 is not fewer than 60. These figures do not correspond with the total number of cases; in one suburb 40 cases were reported by three doctors. Special study is being made of the epidemiology and clinical character of the disease. The disease shows but slight tendency to spread and the mortality is very slight. Experimental comparative studies are in progress, in the Pasteur Institute at Tunis, of dengue, "Marseilles exanthematic fever," and "pustular fever," a disease not yet fully known which has been observed in Tunis in the last 20 years.

Plague.—A severe but localized epidemic of plague occurred from August to October in the neighborhood of Tungliao (also called Payintala) in inner Mongolia. The disease originated in villages north of Tungliao and was carried by people fleeing from the infected villages into the more densely populated area along the railway from Tungliao to Chienchiatien. The Chinese authorities reported 487 deaths from the disease in this area up to the middle of October. By the latter part of October the epidemic had practically come to an end; only eight new cases were reported during the two weeks ended November 10.

In 1917 plague was introduced from Mongolia into certain villages in the Province of Shansi near the Hoang Ho (Yellow River). Outbreaks occurred there in 1919 and in every year since. In 1928 the disease spread considerably and extended into villages in the Lin-Hsien and Hsing-Hsien districts. It was estimated that up to October 20, 1928, about 4,000 deaths from plague had occurred in that area.

The June report of the National Epidemic Prevention Bureau of Peking mentioned a severe plague epidemic with high mortality and a severe epizootic among rats in the Province of Fu-Kien, which includes the coast opposite Formosa, but the localities were not specified.

The usual seasonal increase of plague was evident in Madagascar during October, the majority of the cases occurring as usual in the central part of the island. In Uganda 128 cases of plague were reported in the Eastern Province and Buganda during the month of September, as compared with a maximum for the year of 252 cases in June.

A marked increase of plague occurred in the Bombay Presidency during the four weeks ended October 13; the deaths total 1,860, as compared with 645 during the preceding four weeks. The outbreak was most severe in the district of Satara, but the Dharwar and Nasik districts were also seriously infected.

Eleven cases of pneumonic plague were reported at Carapujio, an inland locality in the Province of Santiago del Estero, Argentina, South America, during October. In the first days of November, 14 plague cases occurred at Canadahonda, an inland locality of the Province of Cordoba. At Asuncion (Paraguay) 3 cases of plague were reported during the first half of October.

Cholera.—Reports indicated that cholera decreased in September and the first half of October in all ports of India. The highest incidence of the disease was recorded in the week ended August 11, when 7,557 deaths were reported. During the week ended October 13 the number of deaths fell to 2,293. A considerable number of cases of cholera were reported in the ports of Madras and Calcutta, where 109 and 87 deaths, respectively, were reported during the five weeks ended November 3. In the same period there were 6 deaths at Bombay, 1 case at Tuticorin, and 1 death at Rangoon.

Cholera has been less prevalent in China during 1928 than in 1927. An outbreak was reported in September among Chinese troops stationed about 10 miles from Tientsin.

Yellow fever.—Two cases of yellow fever occurred at Bahia during the first half of September, and one case on October 23. The steamer Bermini arrived early in October at Santos from Pernambuco with three cases of yellow fever on board. At Bathurst, Gambia, one case was reported on November 2 and one on November 6. A native soldier died from the disease on November 14 in a military training camp at Ouidah, in Dahomey.

Dengue.—The incidence of dengue decreased everywhere in the Mediterranean countries early in November. As the disease was made notifiable in most of the countries only during the epidemic, the reports were very incomplete, but it was evident from the returns that none of the outbreaks in 1928 had been serious outside of Greece. Nevertheless, the disease was rather widespread. In Egypt, from 300 to 500 cases had been reported weekly at Cairo, and a few hundred in the Provinces. At Oran, Algeria, the disease appeared in September and spread widely. The cases were mild, however, and only one death occurred.

Diphtheria in Europe in recent years.—Diphtheria is widespread in all parts of Europe and there has been no decrease in its incidence in recent years. Deaths from the disease have gradually decreased since the middle of the nineties, but there are still nearly 20,000 such deaths in a normal year in Europe outside of Russia. The diphtheria death rate per 100,000 inhabitants in the five years 1922–1926, inclusive, was 10.4 in Scotland; 9.3 in Spain; 8.9 in Ireland; 8.2 in the Irish Free State; 7.9 in England and Wales; 5.7 in Germany;

5.1 in Switzerland; 4.8 in Belgium; and 3.4 in the Netherlands. Mortality from diphtheria was low in all the islands of the western Mediterranean and in the Scandinavian countries. Considerable variation in the distribution of diphtheria mortality is shown in different sections of various countries, which might, in a measure, be due to the enforcement of preventive measures and the promptitude with which serum is administered.

CURRENT STATE MORTALITY STATISTICS

For the information of public-health officials and others interested, the data in the following tables have been compiled from the monthly mortality reports of State health departments for the latest month for which published records are available. Statistics of most communicable diseases are not included, since they are available in other tabulations in the Public Health Reports. Statistics of deaths from other causes are limited for the most part to those causes which appear in the State reports. In the case of States which publish detailed mortality reports each month, the record of only the principal groups of causes and certain important specific causes have been used.

For purposes of comparison, the mortality records for a few preceding years are given, the rates being for the month corresponding to the last month for which the 1928 rate is available.

These tabulations will be enlarged as the current data on mortality from additional States become available.

Monthly State mortality statistics

COURT DECISIONS RELATING TO PUBLIC HEALTH

Ophthalmia neonatorum law construed.—(North Carolina Supreme Court; Covington v. Wyatt, 145 S. E. 673; decided December 12, 1928.) An action for damages was brought against a physician for injury to an infant's eyes caused by the use therein of a 30 per cent solution of silver nitrate. The defendant physician was employed to attend at the birth of plaintiff, the birth taking place in a hospital of the mother's own selection. The nurse assisting at the birth was an employee of the hospital. After the birth the nurse inquired of the defendant whether she should put drops into the baby's eyes, and, receiving an affirmative answer, instilled, while the defendant held open the baby's eyes, drops of a silver nitrate solution obtained from a medicine cabinet maintained by the hospital. The solution used was one of approximately 30 per cent.

A State law relating to the prevention of blindness in infants provided, in one section (sec. 7182, Consolidated Statutes), that it was unlawful for any physician or midwife practicing midwifery to neglect or otherwise fail to instill or have instilled into the eyes of a newborn baby, immediately upon its birth, two drops of a solution prescribed or furnished by the State board of health. The solution prescribed contained 1 per cent of silver nitrate. Other sections of the statute read as follows:

SEC. 7185. It shall be the duty of physicians, midwives, or other persons in attendance upon a case of childbirth in a maternity home, hospital, public or charitable institution, in every infant's eyes, within two hours after birth, to use the prophylactic against inflammation of the eyes of the newborn specified in this article, * * *

Sec. 7186. Whoever being a physician, surgeon, midwife, obstetrician, nurse, manager, or person in charge of a maternity home or hospital, parent, relative, or person attendant upon or assisting at the birth of any infant violates any of the provisions of this article shall be deemed guilty of a misdemeanor, and upon conviction thereof be fined in a sum not less than \$10 nor more than \$50, and, if possessed of the required amount of property, subject to suit by the parent or guardian of the child for damages resulting to the child; and if such a suit shall be brought the establishment of the fact that the physician or midwife did not place the drops in the child's eyes within two hours of its birth shall be accepted as prima facie evidence of the physician's or midwife's responsibility for the injury of the disease to the eye or eyes of the child. * * *

The plaintiff contended that these statutory provisions imposed liability upon the defendant without regard to the question of his negligence. In other words, it was contended that the defendant's duty was absolute. The defendant urged the interpretation that his duty was not absolute but relative, and that neither the letter nor the spirit of the statute authorized a civil action for damages resulting from an effort to obey the law. The supreme court took the view that the duty enjoined was not absolute, saying:

The statutes contemplate diverse contingencies. As we construe them, some of the provisions impose duties in cases of childbirth in the maternity ward of a

hospital; others impose duties when the birth occurs elsewhere. It would seem that the latter class of cases is within the purview of section 7182. * * * The duty of trying to comply with the statutes may be absolute; but this is not equivalent to saying that the statute imposes upon a physician the absolute and unqualified duty of seeing that the solution contains exactly one per cent of silver nitrate. In practical effect the duty, if held to be absolute in this sense, would require of the physician the necessity in every case of preparing his own solution or of analyzing that which should be procured from the most competent and reputable sources. This, evidently, is not the object of the law.

The unlawful act denounced in section 7182 is the delinquency of the physician or midwife; but in section 7185 a duty is prescribed, not only for them, but for other persons in attendance upon childbirth in a maternity home or hospital. By section 7186 any physician, nurse, or other person attendant upon or assisting at the birth of an infant, who violates the provisions of article 14, shall be deemed guilty of a misdemeanor and may be subject to a suit for damages. In the last two sections the prescribed duty is required indiscriminately of the physician, the nurse, and others. But the duty is no more absolute here than under section 7182; the word "absolute" signifying certainty in administering the precise solution prescribed by the State board of health. If the prescribed duty is not absolute in its terms, liability in damages will not necessarily be inferred from failure to instill the prescribed solution, where an effort is made in good faith to comply with the statutes. * *

The plaintiff also alleged negligence on the part of the defendant. The court, however, after reviewing the evidence, stated that "as the hospital undertook to furnish a nurse for the mother, and medicines, appliances, and instruments, there is no evidence which discloses such culpability or malpractice on the part of the defendant as should subject him to liability in damages."

A judgment of nonsuit, entered by the trial court, was affirmed. Collection of garbage by city held to be a governmental function.—
(Oklahoma Supreme Court; Oklahoma City v. Baldwin, 272 P. 453; decided April 3, 1928.) An action to recover damages was brought against the city of Oklahoma City, it being alleged that property damage and personal injury had been sustained by reason of one of the garbage trucks of the city health department having negligently hit the car of the plaintiff. A recovery was had in the trial court, and the city appealed. There was thus presented to the supreme court for decision the question as to whether or not a city, in collecting its garbage, was acting in a governmental or corporate capacity. The court decided that the city, when collecting garbage, was discharging a governmental function, in the performance of which the city was not liable for the negligent acts of its agents.

The contention was made that, because the city charged a fee for the removal of garbage, it was acting in its corporate capacity, but the court stated that it did not think the fact that there was a charge necessarily made the removal a nongovernmental function so as to render the city liable.

DEATHS FROM INFLUENZA AND PNEUMONIA IN LARGE CITIES

Deaths from influenza and pneumonia in 78 large cities during eight weeks ended January 19, 1929. (From the Weekly Health Index, January 23, 1929, issued by the Bureau of the Census, Department of Commerce)

Annual rate per 1,000 population.
 Deaths under 1 year per 1,000 births. Cities left blank are not in the registration area for births.
 Data for 72 cities.

⁴ Deaths for week ended Friday.

In the cities for which deaths are shown by color the colored population in 1920 constituted the following percentages of the total population: Atlanta, 31; Baltimore, 15; Birmingham, 39; Dallas, 15; Fort Worth, 14; Houston, 25; Indianapolis, 11; Kansas City, Kans., 14; Knoxville, 15; Louisville, 17; Memphis, 38; Nashville, 30; New Orleans, 26; Richmond, 32; and Washington, D. C., 25.

PREVALENCE OF DISEASE

No health department, State or local, can effectively prevent or control disease without knowledge of when, where, and under what conditions cases are occurring

GENERAL CURRENT SUMMARY AND WEEKLY REPORTS FROM CITIES

The 98 cities reporting cases used in the following table are situated in all parts of the country and have an estimated aggregate population of more than 31,500,000. The estimated population of the 91 cities reporting deaths is nearly 30,000,000. The estimated expectancy is based on the experience of the last nine years, excluding epidemics.

Weeks ended January 12, 1929, and January 14, 1928

City reports for week ended January 12, 1929

The "estimated expectancy" given for diphtheria, poliomyelitis, scarlet fever, smallpox, and typhoid fever is the result of an attempt to ascertain from previous occurrence the number of cases of the disease under consideration that may be expected to occur during a certain week in the absence of epidemics. It is based on reports to the Puplic Health Service during the past nine years. It is in most instances the median number of cases reported in the corresponding weeks of the preceding years. When the reports include several epidemics, or when for other reasons the median is unsatisfactory, the epidemic periods are excluded and the estimated expectancy is the mean number of cases reported for the week during nonepidemic years.

If the reports have not been received for the full nine years, data are used for as many years as possible, but no year earlier than 1920 is included. In obtaining the estimated expectancy the figures are smoothed when necessary to avoid abrupt deviation from the usual trend. For some of the diseases given in the table the available data were not sufficient to make it practicable to compute the estimated expectancy.

The following table gives the rates per 100,000 population for 98 cities for the 5-week period ended January 12, 1929, compared with those for a like period ended January 14, 1928. The population figures used in computing the rates are approximate estimates, authoritative figures for many of the cities not being available. cities reporting cases had estimated aggregate populations of more than 31,000,000. The 91 cities reporting deaths had nearly 30.000.000 estimated population. The number of cities included in each group and the estimated aggregate populations are shown in a separate table below.

Summary of weekly reports from cities, December 9, 1928, to January 12, 1929-Annual rates per 100,000 population compared with rates for the corresponding period of 1927-28 1 DIPHTHERIA CASE RATES

FOREIGN AND INSULAR

INFLUENZA IN EUROPE

A cablegram from the medical director of the health section of the League of Nations, dated January 25, 1929, states that the epidemic of influenza at Glasgow, Scotland, was increasing, with a general death rate of 45 per 1,000 population for the week ended January 19, 1929. In Berlin, Saxony, and Lower Silesia the disease reached the maximum the middle of January but the death rate was still increasing on January 25. The case mortality rate of a large Berlin sickness insurance society reached 3 per 1,000, but other parts of Germany had lower rates or were not affected. Influenza of a mild form was spreading rapidly in Denmark and southern Norway, and prevalence was stationary in Sweden. Influenza reports from other European countries did not disclose anything abnormal.

CANADA

Provinces—Communicable diseases—Two weeks ended January 12, 1929.—The Department of Pensions and National Health reports cases of certain communicable diseases from provinces of Canada for the two weeks ended January 12, 1929, as follows:

Week ended January 5, 1929

UNION OF SOUTH AFRICA

Rodent mortality.—Localized mortality in veld rodents, mainly Namaqua gerbilles, is reported in Victoria West, and in several other places in De Aar and neighboring districts, also in Kenhardt district. Results of laboratory investigation as to the cause of this mortality have so far been inconclusive. The Deputy Director of the South African Institute for Medical Research is now in the affected area investigating the matter in conjunction with Government officials.

Rabies.—As a result of investigations it has been definitely established that the cause of death of two European boys who were bitten by a red meerkat on a farm in the Wolmaranstad district, on October 30, 1928, and who died on the 20th and 23d of November, was rabies.

During the last eight years, 10 deaths following bites by mongoose, dog, or wild cat, and after illness suggestive of rabies, have been reported. In most of these cases information was received a considerable time after death, so that it was impossible to obtain material for laboratory examination, but in one or two instances where material was procured microscopical examination and biological tests were negative. However, circumstances have raised the suspicion that there is rabies infection over a considerable area of the Union, and investigation is being carried on. People are being warned of the danger of animal bites, and urged to take immediate precautions if bitten.

VIRGIN ISLANDS

Communicable diseases—December, 1928.—During the month of December, 1928, cases of communicable diseases were reported from the Virgin Islands as follows:

St. Thomas and St. John:		St. Croix:	
Dengue	1	Gonorrhea	2
Dysentery	3	Syphilis	1
Gonorrhea	2	Tuberculosis	1
Pellagra	1		
Syphilis	3		
Tuberculosis	1		
Uncinariasis	4		

CHOLERA, PLAGUE, SMALLPOX, TYPHUS FEVER, AND YELLOW FEVER

From medical officers of the Public Health Service, American consuls, health section of the League of Nations, and other sources. The reports contained in the following table must not be considered as complete or final as regards either the list of countries included or the figures for the particular countries for which reports are given:
