PUBLICHEALTH REPORTS

VOL. 47

NOVEMBER 25, 1932

NO. 48

CURRENT PREVALENCE OF COMMUNICABLE DISEASES IN THE UNITED STATES 1

October 9-November 5, 1932

The prevalence of certain important communicable diseases, as indicated by weekly telegraphic reports from State health departments to the United States Public Health Service, is summarized in this report. The underlying statistical data are published weekly in the Public Health Reports, under the section entitled "Prevalence of Disease."

Diphtheria.—The expected seasonal increase of diphtheria continued through the current 4-week period. The number of reported cases (7,685) was, however, only 78 per cent of the number reported for the corresponding period in 1931, and 85 per cent of the number in 1929. For this period in 1930—a more nearly normal year—the number of cases totaled 6,461. Each geographic area reported a lower incidence than was reported for the corresponding period last year. The decreases ranged from 3 per cent in the West North Central to 29 per cent in the Mountain and Pacific areas combined.

Poliomyelitis.—For the country as a whole the incidence of poliomyelitis dropped more than 50 per cent during the current 4-week period as compared with the preceding four weeks. The number of cases (447) was only 25 per cent of the number reported for the corresponding period last year and 22 per cent of the number in 1930. For this period in 1929 the number of cases totaled 459.

A study of geographic areas shows that in the Middle Atlantic States, where the outbreak first occurred, the incidence has dropped to almost a normal level. In all other areas, except the Pacific, where there has been no rise above the usual seasonal increase, the peak seems to have been passed and the general tendency was downward. In the Pacific States, while the number of cases was not high (40), it was the highest reported for any 4-week period for the current year.

¹ From the Office of Statistical Investigations, U. S. Public Health Service. The numbers of States included for the various diseases are as follows: Typhoid fever, 47; poliomyelitis, 48; meningococcus meningitis, 48; smallpox, 48; measles, 45; diphtheria, 47; scarlet fever, 47; influenza, 39 States and New York City. The District of Columbia is counted as a State in these reports.

Measles.—Reports indicated a normal seasonal increase in the incidence of measles during the current 4-week period. The disease seemed to be most prevalent in the States along the Atlantic coast and in the Great Lakes regions. Montana, in the Mountain area, reported a slight outbreak. There the number of reported cases rose from 204 for the preceding 4-week period to 436 for the current period. Other States in that area as well as States in the Pacific area reported little change from the preceding period. For the country as a whole, the number of cases for the current period was 4,452, as against 4,244, 3,930, and 5,573 for the corresponding period in the years 1931, 1930, and 1929, respectively.

Scarlet fever.—The number of cases of scarlet fever increased from 8,293 for the preceding 4-week period to 13,491 for the four weeks ended November 5. Compared with previous years the incidence in the whole reporting area was the highest for this period in four years. Each geographic area, except the Mountain and Pacific areas, showed very significant increases over the corresponding period in the three preceding years. In the Mountain and Pacific areas the number of cases closely approximated the average for preceding years.

Meningococcus meningitis.—The prevalence of meningococcus meningitis remained at about the same low level for the current period that it has maintained during the year. The number of cases (146) was only about 65 per cent of last year's figure for the same period and was less than one-half the figures for 1930 and 1929. In each geographic area the incidence was the lowest in recent years.

Smallpox.—The rise in smallpox incidence during the current period was considerably below the normal seasonal increase. The number of reported cases (184) was only 30 per cent of the incidence during the same period last year, less than one-fourth the number reported for the corresponding period in 1930 and one-tenth the number in 1929. Each geographic area has shared in the favorable situation which has prevailed throughout the current year.

Typhoid fever.—A gradual decline in the number of cases of typhoid fever continued, and for the four weeks ended November 5 there were 2,117 cases reported—approximately 1,500 less than occurred during the preceding 4-week period. The decline was very general. For the country as a whole a lower incidence was indicated than for the same period in any of the three preceding years.

Influenza.—The number of cases of influenza rose from 2,707 during the four weeks ended October 8 to 4,939 for the current 4-week period. Geographic areas showing increases were widely scattered. In the East North Central area 509 cases were reported as against 195 for the preceding period, in the South Atlantic 1,636 cases were reported as against 1,023 for the preceding period, in the Mountain

464 as against 43 for the preceding period, and in the Pacific 1,363 as against 905. Compared with previous years the incidence was the highest for this period in recent years. Each geographic area, except the West North Central, reported an excess in incidence over the same period last year.

Mortality, all causes.—The death rate from all causes in large cities, as reported by the Bureau of the Census, showed a slight rise during the current period over the preceding 4-week period, but it was the lowest for a corresponding period in seven years. The rate for the current period was 10.3, as against 10.6, 11.3, and 11.7 for the years 1931, 1930, and 1929, respectively.

SICKNESS AMONG MALE INDUSTRIAL EMPLOYEES DUR-ING THE SECOND QUARTER OF 1932 ¹

By DEAN K. BRUNDAGE, Statistician, Office of Industrial Hygiene and Sanitation, United States Public Health Service

The frequency of sickness causing disability for eight consecutive calendar days or longer among the male members of industrial sickbenefit associations reporting to the United States Public Health Service was slightly higher in the second quarter of 1932 than during the like period of last year, but lower than the rate recorded for the same months of 1929 and 1930. The lower incidence level of illness (including nonindustrial injuries) in the second quarter of 1931 and 1932 than in the same period of the two earlier years is evidenced by the average rate of 91.0 cases per 1,000 males, as compared with 100.3 in the April to July period of 1929 and 1930. The decrease in sickness frequency which has characterized the record from 1929 to 1931 may be regarded as well maintained during the second quarter of 1932.

TABLE 1.—Frequency of disability lasting eight calendar days or longer in the second quarter of 1932 compared with the same quarter of 1931, 1930, and 1929 (male morbidity experience of 29 industrial establishments which reported their cases to the United States Public Health Service during all four years) a

	4. 0	3. 7	4.6	5. 4				

Except that the rates for 1930 and 1929 cover 27 and 23 companies, respectively, instead of 29 in 1931 and
 1932. The rates for the corresponding period of proceding years differ somewhat from those shown in earlier publications, because data for additional groups have become available in the meantime.
 Exclusive of disability from venereal diseases.

¹ The report for the first quarter was published in Public Health Reports for July 15, 1932,

TABLE 1.—Frequency of disability lasting eight calendar days or longer in the second quarter of 1932 compared with the same quarter of 1931, 1930, and 1929 (male morbidity experience of 29 industrial establishments which reported their cases to the United States Public Health Service during all four years)—Continued

Diseases and disease groups which caused disability. (Numbers in parentheses are disease title numbers from the International List	Annual number of disabilities pe 1,000 men in second quarter of—							
of the Causes of Death, Fourth Revision, Paris, 1929)	1932	1931	1930	1929				
Nonrespiratory diseases Diseases of the stomach—cancer excepted (117, 118) Diarrhea and enteritis (120) Appendicitis (121) Hernia (122a) Other digestive diseases (115b, 116, 122b-129) Rheumatic group, total Rheumatic group, total Rheumatis—acute and chronic (56-58) Diseases of the organs of locomotion (156b) Neuralgia, neuritis, and sciatics (87a) Neurasthenia and the like (part of 87b) Other diseases of the nervous system (78-85, part of 87b). Diseases of the heart and arteries and nephritis (90-99, 102, 130-132) Other genito-urinary diseases (133-138)	1.4 .77 4.0 1.4 3.0 12.8 6.4 3.6 2.8 1.3	50.7 3.8 9.35 2.0 3.1 10.9 6.1 3.3 1.5 1.8 1.6 4.2 2.5 3.3	1.4 3.0 11.7 6.1 3.6 2.0	2.2 3.3 12.4 6.6 3.5				
Epidemic and endemic diseases except influenza (1-10, 12-18, 33, 37, 38, part of 39 and 44). Ill-defined and unknown causes (200). All other diseases (19-22, 24-32, 36, part of 39 and 44, 40-43, 45-55, 59-77, 88, 89, 100, 101, 103, 154-156a, 157, 162). Average number of males covered in the record	2.9 1.6 8.3	2. 7 1. 9 8. 5	3. 4 2. 1 7. 5	3. 1 2. 3 8. 4 164, 108				

For respiratory diseases as a whole the rate during the recent quarter-year was slightly higher than in the second three months of 1931 on account of an increase in the number of cases reported as influenza. In fact, the influenza rate was higher in the second quarter of 1932 than during the like period of any of the preceding three years. Attesting the mildness of these cases, the incidence of pneumonia fell to the lowest level hitherto recorded for the second quarter. The frequency of new cases of tuberculosis of the respiratory system was also exceptionally low. Likewise, gratifying decreases in the rate of death from tuberculosis and from pneumonia among the industrial population of the United States and Canada are reported by the Metropolitan Life Insurance Company. When the rates for bronchitis (acute and chronic), diseases of the pharvnx and tonsils, and for the miscellaneous respiratory diseases included in the category "Other respiratory diseases" are added together, one finds that the total, which might well be regarded as representative of the minor respiratory diseases, was lower in the second quarter of 1932 than during the same period of any one of the three preceding years.

The rate for nonrespiratory diseases as a whole, like that for the respiratory group, was slightly higher in the recent period under review than in the corresponding months of 1931. As compared with that part of 1929 and 1930, which is under consideration, the fre-

² Cf. "Record Health Rate—First Half of 1932." Statistical Bulletin, Metropolitan Life Insurance Ca, vol. 13, No. 7, July, 1932.

quency of claims for illness benefits on account of diseases of the digestive system was lower in 1931 and 1932, the average rate for the second quarter of the latter years being 13.4 cases per 1,000 men as against 16.3 during the second three months of 1929 and 1930. Each of the digestive disease categories shown in the accompanying table participated in the decline with the exception of hernia. A marked decrease occurred in the incidence of diseases of the skin, thus continuing the favorable trend for this group noted in the statistics for 1931 and for the first quarter of 1932.

On the unfavorable side the recent quarter reveals a higher incidence for the rheumatic group and for the "degenerative" diseases (diseases of the heart and arteries, and genito-urinary diseases) than was recorded even in the 1929 period. It is possible, however, that these increases may reflect a shift in the age distribution of the insured, as certain employment records show a larger proportion of younger than of older men dismissed when economic conditions require radical curtailment of working forces.

As pointed out in previous communications, the reporting establishments are scattered all over the United States, with a preponderance of companies located north of the Ohio and Potomac Rivers and east of the Mississippi. Identical companies reported in 1931 and 1932, and in 1929 and 1930 the group was almost the same. The records covered about 134,000 men in the second quarter of 1932, about 154,000 in the same months of 1931, and approximately 165,000 men in 1929 and 1930. Only employed persons are included; no information is available concerning the health of the unemployed. However, without doubt a large number of the men included were employed only part of the time.

COURT DECISION RELATING TO PUBLIC HEALTH

Statutory prohibition against a garbage reduction plant held not to include a garbage incineration plant.—(Maryland Court of Appeals; Stoll et al. v. Mayor and City Council of Baltimore et al., 162 A. 267; decided Oct. 6, 1932.) A State law prohibited the establishment of a garbage reduction plant within a certain specified area. One of the questions presented in the case at bar was whether this statute prohibited the establishment of a garbage incineration plant. The court of appeals decided that it did not, taking the view that the distinction was that a reduction plant conveyed the idea "of so handling a substance as to change its form, usually reduce its volume, and extract something of value from it," while an incinerating plant conveyed a distinct impression that the substance would be consumed and destroyed.

DEATHS DURING WEEK ENDED NOVEMBER 5, 1932

[From the Weekly Health Index, issued by the Bureau of the Census, Department of Commerce]
