## THE INFLUENZA EPIDEMIC OF THE WINTER OF 1943-44 IN THE UNITED STATES: A PRELIMINARY SUMMARY <sup>1</sup>

By DOROTHY F. HOLLAND, Statistician, and SELWYN D. COLLINS, Head Statistician, United States Public Health Service

An outbreak of a mild type of influenza started in Minnesota and the Great Lakes region about the middle of November 1943. From the North Central region as the area of origin, the epidemic spread eastward to New England, the Middle Atlantic States, and Kentucky, Virginia, West Virginia, Delaware, and Maryland, outbreaks being reported subsequently in the Mountain and Pacific States, the Southeast (Central and Atlantic) and, finally, in the West South Central States. The Army as well as the civilian population experienced the epidemic, the direction of spread in the two groups showing general correspondence (1). The peak of the epidemic in the civilian population (considering the country as a whole) occurred during the last week of December and the first week of January. It appears that the epidemic in the Army began to subside somewhat earlier, the incidence rates having shown a decline as of the middle of December except in stations in the South and Southwest, which were the last to experience the outbreak.

The tendency of influenza to occur in pandemic form "in cycles with intervals of several decades" (2) led to general concern that the 1943 outbreak might assume the characteristics of the 1918 pandemic. This early apprehension was increased by the fact that in November, when the first indications of an outbreak were observed in this country, influenza had already attained epidemic proportions in England and Wales. However, the sharp rise in influenza deaths in the 126 great towns of England and Wales in November and December was found to be due not to the virulence of the causative organism, but to a high

<sup>&</sup>lt;sup>1</sup> The United States Public Health Service makes grateful acknowledgment of the cooperation of the Hospital Service Plan Commission, American Hospital Association, and member plans, in making available reports of influenza-pneumonia admissions during the epidemic. Special thanks are extended to the Commission for permission to publish these data.

case incidence. The subsequent course of the outbreak in the United States, as well as the experience of other countries in which influenza has been epidemic in the winter of 1943-44, gives no evidence of a recurrence of the severe type of influenza observed in the 1918 pandemic.

Characteristic features of the disease in the recent epidemic were the sudden onset, moderate prostration, fever, and general pains, followed by marked weakness. The duration has been variously reported as between 3 and 5 days. As a result of the characteristic short duration of the illness, the term "lightning" influenza was used in newspaper reports of the epidemic in England. Complications have been infrequent and usually not serious. The excess mortality associated with the epidemic resulted from the high incidence of cases rather than a high case fatality rate. The laboratory evidence available indicates that the recent outbreak was probably largely due to influenza virus A (S, 4). The type A virus was also identified during the epidemic in England and Wales.

#### MORBIDITY

Total incidence.-It is generally recognized that official reports of influenza cases in this country inadequately describe the actual incidence and severity of the disease and the geographic spread and trend of an epidemic. Influenza is now notifiable in all but 4 States, New Hampshire, Massachusetts, Pennsylvania, and New York; and while reporting is required in New York City, the actual number of cases reported in the recent epidemic was so small as effectively to exclude the entire State from the reporting area. Three States not included in the reporting area. Massachusetts, Pennsylvania, and New York (considering the State as a whole), are populous, containing together about one-fifth of the total population of the country. Officially reported cases of influenza for the country as a whole, and particularly for New England and the Middle Atlantic divisions, are therefore substantially understated by the failure of these States to require its notification. Furthermore, official requirement of notification in no sense insures completeness of reporting. As a result of the mild form of the disease in the recent outbreak, many cases were not attended by a physician, necessarily understating the true incidence. The time lag between the onset of the outbreak and the identification of cases as influenzal in type limits the value of officially reported cases as a measure of epidemic trend. In the recent epidemic, a further limitation resulted from the practice adopted by certain States of estimating the incident cases in the total population on the basis of the experience of selected groups, such as school children or industrial workers.

Notwithstanding these limitations, the weekly trend of the epidemic as indicated by influenza cases reported to the Public Health Service by State health officers is of interest. As is shown in table 1, the incidence in the country as a whole showed a continuous upward trend for a 7- to 8-week period beginning about the middle of November 1943, the rise being particularly marked during December. Subsequent to the week ended January 8, 1944, the decline in incidence has been progressive. The reported case incidence in the recent influenza epidemic appears to have been about of the same order as in the

 TABLE 1.—Telegraphic reports of influenza cases from State health officers to the U. S. Public Health Service, weeks ended Nov. 13, 1943, through Feb. 5, 1944, and the corresponding weeks of 1940-43 compared—all reporting States <sup>1</sup>

	Nur	nber of influen	za cases report	ed

<sup>1</sup> Influenza is not reportable in the following States: Massachusetts, New Hampshire, New York (creept New York City), and Pennsylvania. New Hampshire and Pennsylvania have submitted reports of influenza cases for certain weeks in the period 1940-44; these reports are therefore included but the number of cases is negligible. No reports of influenza cases have been received from Massachusetts in the period considered. The totals include cases for New York City in which influenza is reportable, but no cases for up-State New York were reported in the period considered. Influenza is reportable in Mississippi, but it appears that notification is not enforced, no cases having been reported in the period considered.
 <sup>3</sup> The ending dates of the weeks specified are as of 1943 and 1944. The weeks in the preceding years correspond in number, taking the weeks specified are as of 1943 and 1944. The weeks in the preceding years correspond in number, taking the weeks of the week ended Dec. 18, 1943, was estimated in part and does not represent exclusively cases reported by physicians. The trend in the total cases reported therefore is indicated more exactly if the figures for Kentucky are omitted. The total for the reporting States, exclusive of Kentucky, is as follows: Week ended Dec. 4, 1943, 4,486; Dec. 11, 18,330; Dec. 18, 48,603; Dec. 25, 81,753; Jan. 1, 1944, 105,997; Jan. 8, 103,825; Jan. 15, 63,722; Jan. 22, 46,264; Jan. 29, 21,638; Feb. 5, 14,244. See also footnote 6, table 2.
 In the weeks ended Feb. 12 through Mar. 4, 1944, the incidence of influenza showed some excees over the 1942-43 average for corresponding weeks, the number of cases reported for weeks ended on the specified of the specifi

1912-43 average for corresponding weeks, the number of cases reported for weeks ended on the specified dates being as follows: Feb. 12, 10,748; Feb. 19, 7,189; Feb. 26, 6,425; Mar. 4, 5,249. In the weeks ended Mar. 11 through Apr. 1, the reported cases continued to decline, falling below the 1942-43 average for corresponding weeks.

<sup>3</sup> In the week ended Dec. 25, 1943, Louisiana reported 148 cases, and in the week ended Jan. 1, 1944, 4,136 cases. A later mail report indicated that this marked increase was due in part to a change in the method of reporting cases, the total number of cases seen by physicians being substituted for individual reports of cases by name.

Exclusive of a delayed report of 1,000 cases from Wyoming.

epidemic of 1940-41. However, the 1940-41 epidemic was minor measured in terms of the total excess death rate from influenza-pneumoria (5), while from the standpoint of mortality from all causes the recent epidemic was comparable in severity to that of 1928-29, the major epidemic since the period 1918-20.

Table 2 summarizes the weekly incidence of influenza cases reported to the Public Health Service, by geographic division and State. It should be noted that the trend in incidence may vary widely among the States within a given geographic division, limiting the significance of

the division totals. However, with the exceptions noted in the table, the figures are broadly indicative of the epidemic trend in a given State. Interstate comparisons of the magnitude of the case incidence are not significant due to lack of uniformity among the States in the completeness of notification.

The number of cases for the East South Central Division, exclusive of Kentucky, is as follows: Week ended Dec. 4, 1943, 427, Dec. 11, 591, Dec. 18, 1,277, Dec. 25, 2,555, Jan. 1, 1944, 8,775, Jan. 8, 6,160, Jan. 15, 4,190, Jan. 22, 3,297, Jan. 29, 1,683, Feb. 5, 638.
A later mail report from Kentucky gave an estimated total of more than 35,000 cases for the week ended Dec. 11, 1943, of which an estimated total of 30,000 was included in the telegraphic report for the week ended Dec. 1942.

Poet, 18, 1943. <sup>7</sup> See the first paragraph of footnote 5, table 1. <sup>8</sup> See the second paragraph of footnote 5, table 1.

Hospital incidence.-Through the cooperation of the Hospital Service Plan Commission of the American Hospital Association, the weekly incidence of hospitalized illness due to pneumonia, influenza, and other upper respiratory diseases among beneficiaries of 14 Blue Cross Hospital Service Plans has been made available to the Public The 14 reporting Blue Cross Plans were located in Health Service. metropolitan communities in 11 States, all geographic regions except the Southeast, South Central, and Pacific being represented by at least one plan.

The trend in hospital admissions with a diagnosis of pneumonia, influenza, or other upper respiratory infections shows general correspondence with the trend of the total case incidence (as indicated by reported cases of influenza) in a given area (table 3). Thus, the maximal number of influenza-pneumonia hospital admissions in St. Paul occurred in the week ended December 4, 1943, with a secondary peak This result is consistent with the early peak observed 2 weeks later. in the total incidence of influenza in Minnesota, this State being one of the first to experience the outbreak. The week ended December 18, the peak week in the hospital incidence of influenza-pneumonia as reported by Group Hospital Service, St. Louis, corresponds with the

peak week in total incidence for Missouri, based on officially reported influenza cases. The subsequent spread of the epidemic to the Middle Atlantic States likewise is reflected in the high hospital incidence of influenza-pneumonia in the period December 11-January 1 reported by the Blue Cross Plans in New York City, Buffalo, Syracuse, and Philadelphia. However, the influenza-pneumonia hospital incidence

TABLE 3.—Hospital admissions with a diagnosis of influenza or pneumonia as a percent of total hospital admissions, weeks ended Nov. 6, 1943, through Jan. 29, 1944, as reported to the Hospital Service Plan Commission of the American Hospital Association by representative Blue Cross Hospital Service Plans—data made available to the U.S. Public Health Service

\*No report received for the specified week.

<sup>1</sup> Includes upper respiratory infections.

In November, the weekly average influenza-pneumonia admissions were 3.1 percent of total admissions for this Plan.
 The figures relate to cases paid, not admissions.

based on the combined experience of the reporting plans differs somewhat from the trend of the total incidence, since the Blue Cross data include no representation of the West South Central States.

For the week ended November 6, 1943, in the combined experience of 11 plans, influenza-pneumonia hospital admissions represented 4.7 percent of the total admissions; after a gradual increase during November and December, the proportion reached 17.1 percent in the week ended January 1, 1944.<sup>2</sup> Subsequent reports showed a progressive decline in influenza-pneumonia hospital admissions, their proportion to the total having fallen to 8.3 percent in the week ended January 22 (13 plans reporting). The relative weekly number of influenza-pneumonia admissions was notably high in the experience of Blue Cross Plans in the following cities:

#### MORTALITY

The death rate from all causes during an influenza epidemic is an especially significant measure of its severity, the excess mortality relative to that in a normal (i. e., nonepidemic) period representing deaths associated with the epidemic. Weekly reports of deaths from all causes are made to the Bureau of the Census by 90 major cities with an aggregate population of nearly 40 million (6). Mortality in these cities began to rise early in December 1943, but the excess over the comparable period of preceding years did not become marked until the latter part of the month.

In the 90 cities considered as a group, the provisional death rate from all causes (annual basis) was 13.3 per 1,000 estimated population in the week ended December 4, 1943, and after a continuing rise in succeeding weeks, reached the peak rate of 19.4 per 1,000 in the week ended January 1, 1944, representing an excess of 6.5 deaths per 1,000 over the 1941-42 average for the corresponding week. Throughout the remainder of January, the death rate in this urban population showed a marked downward trend, and has remained approximately at the expected level during February and March.

It may be assumed that a lag of about 1 week occurs between the maximal weekly case incidence and the maximal death rate. Thus, with reference to the trend of the average excess weekly death rate in these 90 cities, the epidemic appears to have reached its maximal incidence between December 18 and 25. However, the period of maximal incidence based on officially reported cases occurred between December 25 and January 8. This lack of correspondence results in part from the virtual exclusion of such populous States as

<sup>&</sup>lt;sup>3</sup> The comparable figure for the week ended December 25, 1943, was 18.7 percent. However, the experience of this week is believed to be atypical since it preceded Christmas, both total hospital admissions and influenza-pneumonia admissions being lower than in the prior and succeeding weeks.

Massachusetts, New York, and Pennsylvania from the reporting area for official notification of influenza cases, cities in these 3 States, on the other hand, being included among the 90 cities reporting Allowance should be made for the added fact that the deaths. death rates are based exclusively on an urban experience.

Comparison of the death rate in these reporting cities grouped by geographic division, as shown in table 4, reveals several points of interest.<sup>3</sup> The epidemic appears to have been somewhat more

TABLE 4.—Weekly actual and excess death rates, all causes, per 1,000 estimated population in 90 major cities of the United States, and weekly excess death rate in the reporting cities grouped by geographic division, for the weeks ended Nov. 13, 1943, through Feb. 5, 1944 <sup>1</sup> (provisional rates)

<sup>1</sup> Computed from telegraphic reports of deaths as published in the Weekly Mortality Index of the U. S. Bureau of the Census, Washington, D. C. Populations used are estimates as of Nov. 1 of 1943, 1942, and 1941 as computed from U. S. Bureau of the Census releases giving estimates of the civilian population by counties as of May 1, 1942 (Series P-3, No. 33, 2-25-43), Mar. 1, 1943 (Series P-3, No. 38, 10-31-43), and Nov. 1, 1943 (Series P-44, No. 3, 2-15-44). Because of considerable shifts in population in 1943, the rates in this table differ considerably from similar rates in the Public Health Reports for Jan. 21 and Feb. 18, 1944, which were prepared before the November 1943 population estimates were available. 3 week moving average of average rates for corresponding weeks of 1941-42 and 1942-43.

3-week moving average of average rates for corresponding weeks of 1941-42 and 1942-43

3. week moving average of average rates for corresponding weeks of 1941-42 and 1942-43.
 Excess over 3-week moving average of average rates for corresponding weeks of 1941-42 and 1942-43.
 4. The same 90 cities are used in all 3 years throughout this table, practically all having populations of 100,000 or more in 1940. The cities classified by geographic division are as follows: New England (14 cities): Boston, Bridgeport, Cambridge, Fall River, Hartford, Lowell, Lynn, New Bedford, New Haven, Providence, Somerville, Springfield, Mass., Waterbury, Worcester; Middle Atlantic (17 cities): Albany, Buffalo, Camden, Elizabeth, Eric, Jersey City, Newark, N. J., New York, Paterson, Philadelphia, Pittsburgh, Rochester, N. Y., Schenectady, Syracuse, Trenton, Utica, Yonkers; East North Central (18 cities): A kron, Canton, Chicago, Cincinnati, Cleveland, Columbus, Dayton, Detroit, Evansville, Flint, Fort Wayne, Grand Rapids, Indianapolis, Milwaukee, Peoria, South Bend, Toledo, Youngstown; West North Central (18 cities): Des Moines, Duluth, Kansss City, Xans, Kansas City, Mo., Minneapolis, Omaha, St. Louis, St. Paul, Wichita; South Atlantic (8 cities): Atlanta, Baltimore, Miami, Norfolk, Richmond, Tampa, Washington, D. C., Wilmington, Del.; East South Central (5 cities): Birmingham, Knoville, Louisville, Memphis, Nashville; West South Central (17 cities): Dallawa, El Paso, Fort Worth, Houston, New Orleans, Oklahoma City, San Antonio; Mountain (2 cities): Denver, Salt Lake City; Pacific (10 cities): Long Beach, Los Angeles, Oakland, Portland. Oreg., Sacramento, San Diego, San Francisco, Seattle, Spokane, Tacoma.

<sup>3</sup> The rates shown in table 4 supersede similar rates published in two earlier numbers of PUBLIC HEALTH REPORTS: Prevalence of communicable diseases in the United States, December 5, 1943-January 1, 1944, Pub. Health Rep., 59: (79-86) Jan. 21, 1944; and Prevalence of communicable diseases in the United States, January 2-29, 1944, Pub. Health Rep., 59; 236-242 (Feb. 18, 1944), which were computed prior to the release of the estimates of the civilian population by county as of Nov. 1, 1943.

severe in southern New England and the Middle Atlantic States than in other divisions, a conclusion not indicated by the case incidence due to the incompleteness of official reports or lack of the requirement for notification of influenza in several States of this region. With respect to the epidemic trend in a given geographic division, the excess death rate in the selected urban population and the incidence based on officially reported cases in most instances are consistent. The secondary peak in the death rate in the West North Central cities occurring in the week ended January 1 is consistent with the peak in incidence for the total population of the division (excluding the Dakotas, whose urban population is not represented in the mortality reports). However, in Minnesota and Missouri the epidemic began to subside earlier than in the other West North Central States, this earlier peak in incidence being reflected in the occurrence of a primary peak in the urban death rate in the week ended December The validity of the trend in case incidence based on officially 18. reported cases in the West South Central States in general is confirmed by the trend in the excess death rate. In the division as a whole, the peak in case incidence occurred in the week ended January 8, being reflected in the persistence of a marked excess death rate in the urban population as late as the week ended January 15. It is believed, however, that incomplete or delayed reporting in certain States of this division has obscured the primary peak in incidence which was followed by the high death rate of the week ended January 1.

For the whole group of 90 large cities, the mortality from all causes in excess of the normal expectancy during the 11 weeks from November 21, 1943 to February 5, 1944, amounted to 50 per 100,000 popula-This figure may be compared with total excess rates from all tion. causes for a group of 35 large cities of 65 per 100,000 for the epidemic of 1928-29; 48 for that of 1926, 50 for that of 1923, 34 for that of 1922, 125 for the epidemic of 1920, and 598 for the pandemic of 1918-19. Comparable data are not available for the several epidemics since 1930, but they were all smaller than those of 1928-29, 1926, and 1923. During the peak week ended January 1, 1944, the excess mortality from all causes in the current epidemic was larger than in the peak week of the epidemic of 1928-29, but the total excess during the whole epidemic was considerably smaller, 50 as compared with 65 per 100,000 for 1928-29. Thus the current outbreak was larger than any epidemic since 1928-29, but caused only about 8 percent as many excess deaths in the United States as the 1918 pandemic.

### EPIDEMIC INFLUENZA OUTSIDE THE UNITED STATES

Epidemics of a mild form of influenza and other upper respiratory infections were reported from many areas of North and South America during the past winter. An outbreak began in Canada about the

middle of November, the trend in incidence corresponding to that observed in Minnesota and the Great Lakes States. On the other hand, the course of the outbreaks in the border States of Mexico was roughly parallel to the epidemic trend in Texas, some areas reporting a peak in incidence about the middle of January, while in other areas the incidence remained high throughout the month. Epidemics were reported in Honduras, Haiti, Jamaica, Martinique, and Curacao in November and December. In Venezuela, widespread epidemics occurred late in November and December, the peak being reached by the middle of January except in certain cities of the interior. Reports of epidemics appearing in British and Dutch Guiana in January suggest that the disease spread from Venezuela to the southeast. An outbreak of influenza started in Recife, on the northeast coast of Brazil, in the middle of December. It is reported that the Brazilian health authorities were greatly alarmed over the possible spread of the epidemic, as a result of which the newspapers published general instructions for the control of influenza, and all vitamin preparations and sulfonamides were officially exempt from import duties for a 6-month period beginning early in January. However, information available to date gives no indication of the extension of the epidemic toward the southern part of Brazil. Southern Brazil, as well as Paraguay, Uruguay, Argentina, and Chile, are now in their summer season, in which outbreaks of respiratory disease are not frequent.

Official reports on the prevalence of influenza in continental Europe are fragmentary. A mild type of influenza has been epidemic in Spain since November, the incidence having declined to normal in January in the provinces from which official reports have been received. A press report via Berne noted the occurrence of a widespread epidemic of influenza in northern Italy in the middle of December. An official report made early in February indicated that influenza was then epidemic in Denmark, France, and Switzerland. With the exception of Tangier and Spanish Morocco, North Africa appears to have experienced no abnormal incidence of influenza during the past winter.

An interesting feature of the epidemic in England and Wales, to which earlier reference has been made, was the action taken to relieve the acute shortage of civilian medical personnel resulting from the war. Early in December, an arrangement was made for the deferment from induction into the Services of some 300 junior house physicians. In addition, the Royal Army Medical Corps made available hundreds of Army doctors to assist in the care of influenza cases among civilians, representing the first instance of such cooperation between military and civilian medical personnel. While the war has caused some depletion of the supply of physicians in the United States, the number of physicians relative to the civilian population is still substantially in excess of the ratio prevailing in England. In Decem-

ber, liaison officers of the United States Public Health Service, at the request of the Surgeon General of the Army, surveyed possible medical needs arising from the influenza epidemic in this country, but the results indicated no need for such emergency action as the English situation required.

## **PREVALENCE OF COMMUNICABLE DISEASES IN THE** UNITED STATES

#### July 16-August 12, 1944

The accompanying table (table 1) summarizes the prevalence of nine important communicable diseases, based on weekly telegraphic reports from State health departments. The reports from each State for each week are published in the Public Health Reports under the section "Prevalence of disease." The table gives the number of cases of these diseases for the 4 weeks ended August 12, 1944, the number reported for the corresponding period in 1943, and the median number for the years 1939-43.

#### DISEASES ABOVE MEDIAN PREVALENCE

Diphtheria.-During the current year the downward trend of diphtheria cases has been interrupted for the first time since 1939. For the 4 weeks ended August 12 there were 713 cases reported, as compared with 607 for the corresponding period in 1943 and a 5-year (1939-43) median of 613 cases. Every section of the country except the Middle Atlantic and East North Central sections showed some increase over the medians, but the greatest excesses were reported from the South Central and Pacific sections.

Influenza.—The number of cases (1,667) of influenza reported during the current 4-week period was only about 75 percent of the number reported for the corresponding period in 1943, but it was about 10 percent above the preceding 5-year median. The New England and South Central sections reported more cases than normally occur

## 1141

in those sections, but in other sections the incidence either closely approximated the median or fell considerably below it.

Meningococcus meningitis.—For the 4 weeks ended August 12 there were 712 cases of meningitis reported. During the corresponding period in 1943 there were 826 cases, and the 1939-43 median was 122 cases; the median was based on 3 nonepidemic and 2 epidemic years. The incidence was lower than in 1943 in all sections except the West North Central and South Central regions, but in all sections the incidence was considerably above the 5-year median. The lowest incidence of this disease is normally reported during the latter part of August and, while the number of cases has been relatively high, the rate of decrease compares favorably with preceding years.

Poliomyelitis.-The number of cases of poliomyelitis rose from 1,100 during the preceding 4 weeks to 3,253 during the 4 weeks ended

TABLE 1.—Number of reported cases of 9 communicable diseases in the United States during the 4-week period July 16-August 12, 1944, the number for the correspond-ing period in 1943, and the median number of cases reported for the corresponding period. 1939-43

<sup>2</sup> Mississippi excluded.

August 12. For the country as a whole the incidence was almost 2 times that reported for the corresponding period in 1943 and more than 4 times the 1939-43 median. Nine states reported more than 75 percent of the total infantile paralysis cases, viz., New York, 1,057 cases; Pennsylvania, 278; Kentucky, 208; North Carolina, 220; Virginia, 167; Ohio, 157; Michigan, 147; Indiana, 99; and Maryland, 80 In some States only the normal seasonal increase occurred, cases. and in many others the reports were not greatly above the usual expectancy. So far every section of the country except the Mountain and Pacific regions has been affected by the current outbreak of this disease, with the largest excesses over the normal expectancy occurring in the Middle Atlantic, South Atlantic, and East South Central regions. In 1943 the first increase in the number of cases occurred in States in the Mountain, Pacific, and West South Central sections, while in 1941 the disease first became epidemic in the South Atlantic and East South Central sections. Table 2 shows the reported cases in geographic areas

TABLE 2.—Number of cases of poliomyelitis reported in each geographic area for recent weeks of 1944 with comparative data for 1943 and 1941 <sup>1</sup>

A similar table for earlier reports appeared in Public Health Reports for Aug. 4, 1944, p. 1024.

during recent weeks of 1944 with corresponding data for 1943 and 1941. In 1942 the number of cases of poliomyelitis was the lowest reported in recent years. For the week ended August 19, 1944, the latest data available, there were 1,250 cases reported. Since the beginning of the year there have been 6,259 cases of poliomyelitis reported as compared with 4,058 for the same period in 1943, 1,505 in 1942, and 3,401 in 1941.

Scarlet fever.—For the country as a whole the incidence of scarlet fever remained at a relatively high level, 3,184 cases being reported for the current 4-week period, as compared with a 5-year median of 2,888 cases. The greatest excesses over the normal seasonal expectancy were reported from the South Atlantic and Pacific regions with minor excesses in the East North Central, West South Central, and Mountain sections; in other sections the incidence was either about normal or lower than the 1939–43 median.

Rocky Mountain spotted fever.—The South Atlantic region continued to report an unusually large number of cases of this disease, but in other sections the incidence was about normal. Of a total of 111 cases, the South Atlantic States reported 71, the Middle Atlantic and East South Central sections, 10 each, with the other sections reporting from none in the Pacific region to 5 each in the East North Central and West South Central sections. During the current period Virginia reported 23 cases, North Carolina 22, Maryland 12, and West Virginia and Georgia 6 each. Tennessee and New York reported 8 and 5 cases respectively, but no other State reported more than 3 cases for the 4-week period.

## DISEASES BELOW MEDIAN PREVALENCE

Measles.—The number of cases (6,201) of measles reported for the 4 weeks ended August 12 was only about one-half of the number reported for the corresponding period in 1943, and slightly more than 10 percent of the 1939–43 median. Increases over the seasonal expectancy were reported from the South Atlantic, West South Central, and Pacific regions, but very significant decreases were reported from the North Atlantic and East North Central regions, where the disease has been unusually prevalent for the past 2 years; minor decreases were reported from the West North Central, East South Central and Mountain sections.

Smallpox.—The smallpox situation was very favorable, 21 cases being reported for the current 4 weeks, as compared with 23 in 1943 and a 5-year median of 29 cases. Nine of the 21 cases occurred in the West North Central region, 4 each in the East North Central and South Atlantic regions; 4 other regions reported 1 case each, and none occurred in the North Atlantic region. Typhoid and paratyphoid fever.—The incidence of this disease was also relatively low, the number of cases (688) being about 75 percent of the number reported in 1943 and less than 60 percent of the preceding 5-year median. With one exception, the New England region, the incidence was considerably below the normal seasonal incidence in all sections of the country.

Whooping cough.—The number of cases (9,438) of whooping cough reported was the lowest for the corresponding period in recent years. The preceding 5-year median for this period was approximately 14,600 cases. The number of cases occurring in the South Atlantic section was about 20 percent above the seasonal expectancy, and in the West North Central, East South Central, and Mountain sections the numbers of cases were about normal, but in each of the other 5 sections the incidence was the lowest in the 7 years for which these data are available.

## MORTALITY, ALL CAUSES

For the 4 weeks ended August 12, there were 32,044 deaths from all causes reported to the Bureau of the Census by 93 large cities. The average number of deaths reported for the corresponding weeks in the 3 preceding years was 31,787. For the first two weeks of the period the number of deaths was below the preceding 3-year average; during the third week the number of deaths was about 4 percent above the average, and for the last week the number reported was approximately the same as the average. Cities in the North Atlantic, South Central, Mountain, and Pacific regions reported slight increases over the 3-year average, while those in the South Atlantic and North Central sections reported fewer deaths.

## DEATHS DURING WEEK ENDED AUGUST 19, 1944

[From the Weekly Mortality Index, issued by the Burcau of the Census, Department of Commerce]

- ·	Week ended Aug 19, 1944	Correspond ing week, 1943

## **PREVALENCE OF DISEASE**

No health department, State or local, can effectively prevent or control disease without knowledge of when, where, and under what conditions cases are occurring

## UNITED STATES

## REPORTS FROM STATES FOR WEEK ENDED AUGUST 26, 1944 Summary

A total of 1,529 cases of poliomyelitis was reported as compared with 1,254 last week, 1,014 for the next earlier week and 872 for the corresponding week last year. The current figure is the largest number of cases reported for a corresponding week since 1927, the earliest year for which weekly reports are available, and probably the largest since 1916. Increases occurred in all of the nine geographic areas except the West South Central and the Pacific. The largest numbers were reported in the Middle Atlantic, North Central, and South Atlantic areas, aggregating 1,345 cases, or 88 percent of the total. In these sections, the smallest numerical increase occurred in the South Atlantic area.

Fifteen States reported 19 or more cases each, as follows (last week's figures in parentheses): *Increases*—Massachusetts 43 (30), Connecticut 19 (15), New York 581 (469), New Jersey 36 (24), Pennsylvania 139 (108), Ohio 97 (92), Illinois 38 (34), Michigan 94 (55), Wisconsin 26 (11), Minnesota 57 (38), Maryland 40 (27), District of Columbia 27 (19), Kentucky 38 (35); decreases—Virginia 63 (66), North Carolina 46 (48).

The cumulative total for the year to date is 7,789, as compared with 4,930 and 6,398, respectively, for the corresponding periods last year and in 1931. The cumulative total to date this year is apparently the largest number reported for the period since the epidemic of 1916.

The incidence of meningococcus meningitis continues high. To date a total of 13,248 cases has been reported, as compared with 13,694 for the same period last year, and a 5-year (1939-43) median of 1,441 cases. The largest numbers of cases are being reported in the Middle Atlantic and East North Central areas.

With the exception of poliomyelitis and meningitis the incidence of the important communicable diseases is at about normal expectancy. Endemic typhus fever is somewhat above last year's figures—a total of 2,934 cases has been reported to date as compared with 2,341 for the same period last year. The highest incidence is being reported in Georgia, Texas, Alabama, and North Carolina. For the current week cases were reported in only 11 States, all in the South Atlantic and South Central areas.

The number of deaths in 93 large cities dropped sharply during the week—from 8,681 to 7,472. This latter figure is below the 3-year (1941-43) median of 7,509.

## Telegraphic morbidity reports from State health officers for the week ended August 28, 1944, and comparison with corresponding week of 1943 and 5-year median

In these tables a zero indicates a definite report, while leaders imply that, although none was reported, cases may have occurred.

\*Period ended earlier than Saturday. \*5-year median, 1939-43.

those for prior years, especially for certain diseases. Each State health officer has been requested to include in the monthly report for his State all diseases that are required by law or regulation to be reported in the State. The lists of diseases required to be reported are not the same for each State. Only 12 of the common communicable diseases are notifiable in all the States. In some instances cases are May, and June 1944. These reports are preliminary and the figures are therefore more or less incomplete. In most instances they include cases reported in both civilian and military populations. The comparisons made are with similar preliminary reports; but owing to population shifts and the presence of large military populations in certain States, the figures for some States are not comparable with reported, in some States, of diseases that are not required by law or regulation to be reported, and the figures are included although manifestly incomplete. There are also variations among the States in the degree of completeness of reporting of cases of the reportable diseases. As compared with the deaths, incomplete case reports are obvious for such diseases as malaria, pellagra, pneumonia, and tuberculosis, while in many States other diseases, such as puerperal septicemia and Vincent's infection, are not reportable. The figures in the following table are the totals of the monthly morbidity reports received from the State health authorities for April

In spite of these known deficiencies, however, these monthly reports, which are published quarterly and annually in consolidated form, have proved of value in presenting early information regarding the reported incidence of a large group of diseases and in indicating a trend by providing a comparison with similar preliminary figures for prior years. To some extent they also give a picture of the geographic prevalence of certain diseases, as the States are arranged by geographic location.

Leaders are used in the table to indicate that no case of the disease was reported.
