THE PREPARATION OF SLIDES FOR MEASUREMENT OF DUST PARTICLE SIZE ¹

By W. E. McCORMICK,² *Passed Assistant Chemist (R), United States Public Health Service*

The determination of the particle size of atmospheric dusts of unhygienic significance is frequently necessary in order to evaluate properly the health hazard arising from a given dusty operation or process. The prevailing method now in use for making this determination is to measure microscopically (by either a filar micrometer or a microprojector) a sufficient number of particles (usually 150 to 200) of the atmospheric dust, and then to determine graphically the geometric mean size and standard deviation (1, 2, 3).

At least three methods have been used frequently by industrial hygienists for obtaining the dust specimen for measurement. These are:

1. Deposition of the dust directly from the workroom atmosphere onto a microscope cover slip by the Owens jet dust counter (1, 4).
2. Evaporation of a drop of the impinger dust sample solution on a microscope slide (1, 4).
3. Preparation of a microscope slide by Green's method from a small portion of dry dust mixed with a vehicle such as turpentine (5).

For some dusts all of these methods are unsatisfactory and are open to criticism.

Bloomfield (4) and Bloomfield and Dalla Valle (1) found agreement existing between the first two methods, but favored the use of the first because of the greater simplicity both of collection of the dust and of final preparation of the specimens. The dusts used by them, however, for comparative purposes, were of the nonfibrous types, and possessed, for each individual sample, fairly uniform particle sizes. With dusts of the fibrous types, such as that found in asbestos textile

¹ From the Industrial Hygiene Division.

² On detail to the Division of Industrial Hygiene, North Carolina State Board of Health, Raleigh, N. C.

manufacturing plants, where both the fiber size and content may be of industrial health significance, it is questionable whether the Owens instrument obtains samples which are representative of the workroom atmosphere. The instrument has been used for studies of this type (6), but more data appear to be needed to determine its reliability with this type of dust. It is known that the instrument is selective for particles below 2 microns (1, p. 36). In a few preliminary comparative tests recently made by the author on slides prepared from asbestos dust both by the Owens dust counter and by the evaporation method, it has been observed that a considerably lower percentage of fibers existed on the Owens slides. The exact explanation for this is not known, although it might be due to the greater difficulty in wetting the larger asbestos fibers by the method used in this instrument (by moisture condensation on the dust due to the high velocity and the resulting cooling of the moisture-saturated air in passing through the slit), and thus decreasing their ability to adhere to the glass cover slip.

Slides prepared by the second method are not wholly satisfactory, when dealing with fibrous dusts, due to the tendency to agglomeration of the particles and fibers. This frequently renders the particles on the slide very difficult or impossible to measure.

Green's method utilizes dry dust collected either by the filter bag method of Hatch (7), or from rafters and ledges in the workroom atmosphere. Silverman and Franklin (8), however, have shown that this method of slide preparation tends to disintegrate the more fragile particles, and is not satisfactory for particle size measurements of industrial dust.

The author has used for some time a method of slide preparation which overcomes the above objections. Although no advantage for it is claimed over the first two methods for dusts of either the non-fibrous or nonagglomerating types, it is equally applicable to them. In brief, the method involves the settling of the suspended dust (from a liquid medium) onto the surface of a No. 1 microscope slide cover glass, allowing the suspending liquid to evaporate slowly to dryness, and then mounting the cover glass, dust side down, onto a microscope slide for later examination and measurement. The dust deposit, thus being on the underside of the cover glass, can be sharply focused and measured by oil immersion.

Either the Dunn dust-counting cell (9) or the modification of this cell recently described (10) is used as the settling chamber. The No. 1 cover glass (1-inch circle or square) is used as the base. The cell is filled with a small portion of the impinger sample, and covered with a 1- by 3-inch microscope slide. Evaporation of the liquid is allowed to proceed spontaneously. It has been found that just barely "cracking" the cell, by sliding the edge of the microscope

FIGURE 1.—Photomicrographs of asbestos dust made at 500X from slides for which the settling technique of dust deposition was used.

slide to the edge of the cell hole, will aid in the evaporation without permitting entrance of extraneous atmospheric dust. A practical means of accomplishing the settling and evaporation is to permit it to proceed overnight. The dust is thus evenly dispersed over a circular area of about 22 mm. in diameter on the floor of the cell (the No. 1 cover glass).

Upon complete evaporation of the liquid, the glass spacer of the cell is carefully removed and the downturned surface of the microscope slide placed on the upturned surface of the cover glass, so that the area of the slide which covered the cell hole is superimposed over the dust deposit. In this way extraneous contamination is avoided. The slide and cover both can then be inverted as a unit, and the cover firmly cemented to the slide with any of the common microscopic mounting materials for future examination and measurement. If it is desired to mount the dust specimen in a suitable liquid medium for either particle size or refractive index measurements, the cover glass can be cemented at only a few spots, and the medium can then be carefully flowed in between the cover and slide while in the mounted position.

It is very important in preparing the slides, in order to obtain even distribution of the dust without agglomeration, that all parts be clean. The following sequence of cleaning operations has been found to be satisfactory: Scrubbing with soap and water, rinsing with water, immersing in dichromate-sulfuric acid cleaning solution for 10 to 15 minutes, rinsing several times with tap water, and finally rinsing with 95 percent alcohol. The glass parts should be handled only with forceps after immersion in the cleaning solution, inasmuch as the perspiration and the oils from the skin will cause grease contamination and will interfere with uniform distribution of the dust particles.

Figure 1 shows photographs (500X) made of asbestos dust, collected by an impinger, with the slides made by the above method. The photographs illustrate the uniformity of distribution and discreteness of the particles and fibers.

Ethyl alcohol (95 percent) has been used as the collecting medium and the impinger as the method of collection in all of the slide preparations made by the author by this method. However, the method is equally applicable to samples collected by the electrostatic precipitator, or to dry dust samples, suspended in a suitable liquid.

COMPOSITION OF SOME TRADE NAME SOLVENTS USED FOR CLEANING AND DEGREASING, AND FOR THINNING PAINTS ¹

By ALLEN D. BRANDT, *Senior Sanitary Engineer, United States Public Health Service*, W. J. McCONNELL, *Colonel Medical Corps, Army of the United States*, and R. H. FLINN, *Senior Surgeon, United States Public Health Service*.

As a result of a series of acute cases of systemic poisoning, with one fatality, among workers using solvents at a shell- and bomb-loading plant, it was decided to make available to the explosives plants² useful information on the composition and relative toxicity of many of the trade name solvent products used in these establishments. By means of questionnaires to approximately 90 Government-owned explosives manufacturing, loading, and storing plants a roster was obtained of all solvents in current use. From this list approximately 200 representative products were selected for chemical analysis. Samples of the selected products were sent by the respective establishments to the Army Industrial Hygiene Laboratory or to the Industrial Hygiene Division of the United States Public Health Service for chemical analysis.³ The results of these analyses were then compiled into a solvent index which contained all the pertinent data in a form which would permit their convenient use by the personnel of the plant, medical, safety, and engineering departments.

Since many of the products investigated are used also by many other industries it was deemed advisable to make the information available generally to everyone interested in industrial hygiene. It must be remembered, however, that the composition of the various products, as given in tables 1, 2, and 3, is the composition of the

¹ From the Industrial Hygiene Branch, Safety and Security Division, Ordnance Department, Army Service Forces.

² Plants assigned to the Safety and Security Division, Office of the Chief of Ordnance for production security inspection.

³ The authors are indebted to Mr. A. N. Setterlind, of the Division of Industrial Hygiene, Illinois Department of Public Health, and to Mr. D. E. Rushing, of the Industrial Hygiene Division, U. S. Public Health Service, for their suggestions and assistance in the classification of the ingredients of these trade name products. Acknowledgment is made also of the large amount of work done by personnel of the Army Industrial Hygiene Laboratory and the Industrial Hygiene Division, U. S. Public Health Service, in analyzing the samples.

specific sample analyzed and may represent accurately only one lot of the product. Manufacturers of materials of this type frequently change the ingredients or the proportions thereof for various reasons. Consequently, there is no assurance that these products would be exactly the same if purchased today as they were during the second quarter of the present calendar year (1945) when the analyses were made. The only way to be certain of the composition of products of this nature is to analyze a sample from each lot number as received. On the other hand, the general make-up of many of the products listed in tables 1, 2, and 3 will remain remarkably similar since the ingredients are selected by the manufacturers primarily on a functional basis.

The substances analyzed have been classified alphabetically under the names submitted by the users in tables 1, 2, and 3. The names of the suppliers or manufacturers are also given. The supplier or manufacturer listed is the one given by the plant using the particular substance and many of the products listed are available from other sources. The first column contains an index number which serves to identify the material for convenient reference in table 4.

It should be emphasized that the supplier or manufacturer listed in the tables is the one given by the plant which submitted the sample. Most of these same products can be obtained from a large variety of other suppliers. To obtain a fairly complete list of the suppliers would have required a prohibitive amount of time. Consequently, only the one from which the material was actually purchased is listed, with the thought that other plants which desire to use any of these products can obtain the names of the nearby dealers by writing to the one listed in the table.

The samples analyzed were divided into three groups according to their composition and use. In table 1 are listed the substances which are used as cleaners and degreasers, and which are composed mainly of organic solvents. In table 2 are listed the substances which are used as thinners for paints, lacquers, and other finishing materials. The ingredients of these also are largely organic solvents. The miscellaneous materials which are used chiefly as cleaners, degreasers, and protective coatings, and which contain relatively little organic liquid are listed in table 3. Table 4 is a reference table which contains a list of the various substances used by different plants according to mode of use or type of operation at which employed.

The organic liquid components of the products listed in the first three tables are divided into four all-inclusive groups chemically, which are physiologically more or less distinct. They are as follows:

1. **AROMATICS:** These materials are very toxic. The common ones have maximum allowable concentrations of 50 to 200 p. p. m. Examples are benzene, toluene, and xylene.

2. **HALOGENATED HYDROCARBONS:** These chemicals also are very toxic. Most of those encountered in the group of samples analyzed have maximum allowable

concentrations in the range of 50 to 200 p. p. m. Examples are carbon tetrachloride, trichloroethylene, and dichlorobenzene.

3. ALCOHOLS, ESTERS, ETHERS, AND KETONES: These chemical groups are less toxic than 1 and 2. Most of those encountered in the samples analyzed fall into a maximum allowable concentration toxicity range of 200 to 400 p. p. m. Examples are acetone, methyl ethyl ketone, the alcohols, and the acetates.

4. PARAFFINS AND NAPHTHENES: This group is not particularly toxic. It includes materials such as gasoline, Stoddard solvent, petroleum naphtha, and V M and P naphtha. The maximum allowable concentrations for the materials in this group range from 500 to 1,000 p. p. m.

In addition to the substances described in paragraphs 1, 2, 3, and 4 above, some of the products listed in table 3 contain other ingredients. These are of little concern, as a rule, from the inhalation viewpoint but are of importance as regards skin contact. Free alkali and various acids may produce burns or dermatitis if brought in contact with the skin, and others may act as sensitizers and cause allergic eczema.

The results of the analyses were classified as described above because it was felt that this arrangement would be more useful to the majority of personnel than would the actual specific analyses. Hence, an estimate of the danger associated with using a given product may be obtained by noting what percentages of the ingredients fall in the more toxic groups, and observing the boiling range. It should be emphasized that for many operations the boiling range is important and high boiling products should be selected in preference to low boiling ones since, other things being equal, the natural evaporation rate decreases as the boiling point increases and the atmospheric concentration of the vapors of the ingredients will therefore be lower with the higher boiling products.

The data contained in tables 1, 2, and 3 make it possible for personnel of the medical and safety departments to estimate the degree of hazard associated with the use of any of the products investigated; and those in table 4 make it possible to select a less toxic substitute for the same operation.

Even though the data in this paper pertain largely to the health hazard associated with the use of these materials, it must be remembered that most solvents, thinners, and cleaners with the exception of the halogenated hydrocarbons also present important fire and explosion hazards. As a rule the proper control of the health hazard will automatically control the fire or explosion hazard but such is not always the case. It is necessary, therefore, that adequate precautions be taken to prevent the existence or creation of a fire hazard. The potential fire and explosion hazard is influenced greatly by the flash point and by the boiling point of the material used; hence these factors as well as the toxicity must be taken into consideration when selecting the best product for a given operation or use.

TABLE 3.—Materials or products used for cleaning, degreasing, cementing, or finishing operations

Code No.	Name or trade name of material	Composition 1										Boiling range (° C.)	Supplier or manufacturer
		Aromatic hydrocarbons (mac. p. p. m.)	Halogenated hydrocarbons (mac. 50-200 p. p. m.)	Alcohols, esters, ketones (mac. 200-400 p. p. m.)	Paraffins and naphthenes (mac. 500-1,000 p. p. m.)	Free alkali	Alkaline salts	Detergents and soap	Water	Other

Finishing ordnance material.....	C-3, C-11, M-1, M-9, M-13, M-24.		
Grease removal.....	C-1, M-18.		
Ink remover.....	C-16, C-25, C-42, C-60, T-43.		
Lacquer remover.....	C-42, C-57, C-60, T-13.		
Metal sealing.....	M-12.		

TUBERCULOSIS MORTALITY IN EACH STATE, 1944

The Bureau of the Census, on February 1, 1946, released the figures showing the number of deaths from tuberculosis (all forms) in each State and the death rates for 1944. In the table below are shown the number

Number of deaths from tuberculosis (all forms), death rates, and percent changes in rates, by State: United States, 1939-41 average, 1942, 1943, and 1944

[By place of residence]

Area	Number of deaths				Rate per 100,000 population				Percent change in rates		
	1944	1943	1942	1939-41 average	1944	1943	1942	1939-41 average	1943 to 1944	1939-41 to 1944	1939-41 to 1942-44
United States.....	54,731	57,005	57,690	60,429	41.3	42.6	43.1	45.8	-3.1	-9.8	-7.6

of deaths and the death rates for each of the three war years, 1942, 1943, and 1944, and the average rate for the prewar period, 1939-41. In addition, the percentage changes in the rates from 1943 to 1944 and from 1939-41 to 1944, as well as the changes in the average rates from 1939-41 to the average rate for the period 1942-44 are shown.

A detailed report and analysis of all the mortality data for 1944 will be presented in a joint publication by the Division of Vital Statistics, United States Bureau of the Census, and the Tuberculosis Control Division, United States Public Health Service, in the April 5 issue of Public Health Reports.

DEATHS DURING WEEK ENDED JANUARY 5, 1946

[From the Weekly Mortality Index, issued by the Bureau of the Census, Department of Commerce]

	Week ended Jan. 5, 1946	Correspond- ing week, 1945
Data for 93 large cities of the United States:		
Total deaths.....	11, 928	9, 786
Average for 3 prior years.....	11, 353	-----
Deaths under 1 year of age.....	644	592
Average for 3 prior years.....	701	-----
Data from industrial insurance companies:		
Policies in force.....	67, 179, 698	66, 913, 713
Number of death claims.....	10, 576	10, 427
Death claims per 1,000 policies in force, annual rate.....	8. 2	8. 1

PREVALENCE OF DISEASE

No health department, State or local, can effectively prevent or control disease without knowledge of when, where, and under what conditions cases are occurring

UNITED STATES

REPORTS FROM STATES FOR WEEK ENDED JANUARY 12, 1946

Summary

The incidence of influenza declined in all of the 9 geographic divisions except the Mountain and the Pacific, in which areas totals respectively of 4,028 and 871 cases were reported. A total of 32,635 cases was reported for the country as a whole as compared with 48,041 last week, 4,132 and 65,649, respectively, for the corresponding weeks of 1945 and 1944, and a 5-year (1941-45) median of 4,330. Of 17 States reporting 200 or more cases for the week, only 5, with an aggregate of 5,217 cases, reported increases. These are as follows (last week's figures in parentheses): Arkansas 1,249 (1,204), Idaho 823 (79), Colorado 209 (195), Utah 2,284 (1,114), California 652 (436). The total for the first 2 weeks of the year is 80,676, as compared with 8,719 and 192,355 for the first 2 weeks of 1945 and 1944, respectively, and a 5-year median of 8,719.

A total of 262 cases of meningitis was reported, as compared with 189 last week, 645 for the corresponding week of 1944, and a 5-year median of 251 (reported for the corresponding week last year). States reporting more than 10 cases each are as follows (last week's figures in parentheses): New York 28 (14), New Jersey 11 (15), Pennsylvania 16 (7), Ohio 15 (10), Illinois 27 (9), Mississippi 13 (1), Texas 14 (13), California 23 (21). The total for the year to date is 451, as compared with 489 and 1,225, respectively, for the same periods of 1945 and 1944.

One case of dengue fever was reported for the week in Oregon.

A total of 11,668 deaths was recorded during the week in 93 large cities of the United States, as compared with 11,928 last week, 9,912 for the corresponding week of 1945 and a 3-year (1944-45) average of 10,642. The total for the first 2 weeks of the year is 23,596, as compared with 19,698 for the corresponding period last year.

Telegraphic morbidity reports from State health officers for the week ended January 12, 1946, and comparison with corresponding week of 1945 and 5-year median

In these tables a zero indicates a definite report, while leaders imply that, although none was reported cases may have occurred.
