DATE OF RELEASE: JUNE 13, 1969 - ATLANTA, GEORGIA 30333

EPIDEMIOLOGIC NOTES AND REPORTS GROUP A MENINGOCOCCAL MENINGITIS Boston, Massachusetts

Since the first report of a case of Group A meningococcal infection to NCDC since 1967 last week (MMWR, Vol. 18, No. 22), two cases have been notified from Boston City Hospital. One case was in a 6-year-old boy hospitalized on May 24 with a 24-hour history of vomiting, progressive irritability, and neck pain. Physical examination revealed a febrile (101.4°F.), normotensive, semicomatose boy with nuchal rigidity and generalized petechiae. A lumbar puncture yielded cloudy cerebrospinal fluid, and gram negative intracellular diplococci were seen on microscopic examination. Intravenous penicillin was given and within 48 hours, the boy was afebrile and alert. Group A *Neisseria meningitidis* was isolated from

two blood cultures as well as the cerebrospinal fluid.

The other case was in a 50-year-old man admitted on May 27 with a 16-hour history of headache and progressive obtundation. On physical examination, the patient was febrile (100.6°F.) but normotensive and no petechiae were seen. He was semicomatose and combative with marked nuchal rigidity. Lumbar puncture revealed turbid cere-

GROUP A MENINGOCOCCAL MENINGITIS — (Continued from front page)

brospinal fluid with a cell count of 8,700, all of which were polymorphonuclear leukocytes on smear. Gram negative intracellular diplococci were seen on staining the cerebrospinal fluid, and intravenous penicillin was begun. Despite a series of grand mal seizures shortly after admission, the patient rapidly improved and was alert and afebrile 36 hours after admission. Group A *N. meningitidis* was isolated from the cerebrospinal fluid.

Both meningococcal isolates were sensitive to sulfadiazine being inhibited at/or below concentrations of 0.78 µg per ml (0.78 mg percent).

No connection could be established between these two persons, and no further cases of Group A meningococcal infection have occurred to date at Boston City Hospital.

(Reported by Lawrence Stolberg, M.D., I and III Medical Service, William Cranley, M.D., Pediatric Service, Miss A. Kathleen Daly, Chief Bacteriologist, and Maxwell Finland, M.D., Hospital Epidemiologist, Boston City Hospital; Nicholas J. Fiumara, M.D., M.P.H., Director, Division of Communicable Diseases, Massachusetts Department of Public Health; and an EIS Officer.)

TULAREMIA — Addison County, Vermont

During the second and third weeks of April 1969, 13 symptomatic, serologically confirmed cases of tularemia were reported from Addison County, Vermont. This was the same area where in the spring of 1968, 47 cases had occurred in persons handling muskrats during the trapping and shooting season. The 1968 outbreak was the largest outbreak of human tularemia associated with aquatic mammals ever reported in North America.¹ As in 1968, all cases were in muskrat handlers. These 13 persons developed illnesses characterized by painful, slowly healing hand sores, local lymphadenopathy, and fever and were found to have agglutination titers against *Francisella tularensis* of 1:320 or greater. In addition to these 13 cases, one trapper had inapparent infection demonstrated by a rise in titer. This asymptomatic case and two of the symptomatic cases in 1969 had been included in a serologic survey during the 1968 outbreak; all three had been seronegative at that time.

In a survey conducted during May and June 1969 of 30 muskrat handlers not known to be infected, three persons who denied symptoms were found to have diagnostic tularemia agglutination titers of 1:160 or greater. These three individuals were not contacted by survey in 1968 and may have been infected at that time or earlier or may represent inapparent infections in 1969.

All persons with significant antibody had trapped in three areas which were the principal sources for cases

in the preceeding year's epidemic: Otter Creek, its principal tributary Dead Creek, and Little Otter Creek, all of which flow into the eastern shore of Lake Champlain. In some instances, trappers ill in 1969 took animals from the identical legally demarcated trapping areas where patients with tularemia in 1968 had trapped. As in 1968, there was no evidence of an animal epizootic; on the contrary, muskrats were in great abundance and the fur was considered of high quality. In 1968, *F. tularensis* had been cultured from 5 percent of the muskrats as well as mud and water in one trapping area.

Of the 47 patients diagnosed as cases of tularemia in 1968, 14 were known to have trapped again in 1969. One person in this group developed hand sores, local lymphadenopathy, and a fever of several days duration. Two agglutination titers over a 3-week period showed no change, and fluorescent antibody studies on exudate from his skin lesions were equivocal.

(Reported by Linus J. Leavens, M.D., Director, Bureau of Communicable Disease Control, and Dymitry Pomar, D.V.M., Director, Bureau of Laboratories, Vermont State Department of Health; the Bacterial Chemistry Unit and Bacterial Immunology Unit, Laboratory Division, NCDC; and a team of EIS Officers.)

TYPHOID FEVER — Oregon

Late in April 1969, typhoid fever was diagnosed among six members of a missionary family that was visiting in Portland, Oregon, enroute from the Philippines to North Dakota. The family left Cebu City on April 7 after a 4-year tour of duty. They stayed in Pasay City, Manila, from April 7 through 10, and stopped in Hong Kong and Japan between April 10-11 and in Honolulu on April 12. On April 10 the father had developed febrile gastroenteritis and by April

16 five other members had similar illnesses. When examined in Portland, four members had temperatures of 102-105°F. and appeared acutely ill. Two of these four were extremely weak and delirious and had rashes thought to be rose spots. The father and a 10-year-old daughter were afebrile but weak. *Salmonella typhi*, phage type B₁ was isolated from blood and/or stool cultures from all six members. The patients were treated with chloromycetin. Three of the

six were treated for less than 10 days and had relapses. Chloromycetin was recommended for them for an additional 14 days.

The source for the family's infection has not been confirmed. However, while they stayed in Pasay City, they admitted drinking from the city's water supply even though they had been warned that it was contaminated. (Reported by Mrs. Vivien Runte, R.N., Epidemiology Nurse, and Clifford Cookson, and Mrs. Brigitte Metcalf, Microbiologists, Oregon State Board of Health; David Johnson, M.D., D.V.M., M.P.H., Associate Professor of Public Health and Preventive Medicine, University of

Oregon; John Donnelly, M.D., M.P.H., Multnomah County Health Officer; and an EIS Officer.)

Editorial Comment:

The World Health Organization Weekly Epidemiological Record recently reported several outbreaks of typhoid fever in Manila.¹ Between February 17 and April 4, 35 suspected cases were reported from Pasay City, Manila, and by April 10, 28 suspected cases and four deaths had been recorded in the Tondo district of Manila.

FOLLOW-UP HUMAN RABIES – San Diego County, California

Rabies has been confirmed in the 2 1/2-year-old boy in San Diego County bitten by a rabid bobcat on April 1, 1969 (MMWR, Vol. 18, No. 18). Nervous tissue obtained on May 9 was positive by fluorescent rabies antibody staining. Indirect fluorescent antibody titers for rabies on April 24 and May 9 on sera obtained after the child's course of duck embryo vaccine, were 1:64 and 1:2,048, respectively, and on cerebrospinal fluid obtained on April 25 and May 9 were 1:8 and 1:512, respectively. Cultures of nervous tissue, saliva, cerebrospinal fluid, urine, stool, throat, and endotracheal washings have been negative for virus. Mouse inoculation tests on nervous tissue and saliva are still in progress.

The boy has remained comatose since April 27, is areflexic, and his breathing is maintained by a respirator. An electroencephalogram on May 27 was nearly isoelectric indicating profound cerebral damage.

(Reported by George L. Humphrey, D.V.M., Acting Chief, Veterinary Public Health, and Richard Emmons, M.D., Public Health Medical Officer, Bureau of Communicable Diseases, California Department of Public Health; J. B. Askew, M.D., Health Director, and Donald Ramras, M.D., Assistant Health Director, San Diego County Health Department; V. Robert Allen, M.D., Attending Pediatrician, and Edwin Protas, M.D., Pediatric Resident, University Hospital of San Diego County.)
