ARTHROPODBORNE ENCEPHALITIS - United States 1969
Despite increased rainfall earlier this year, there have been no outbreaks among humans of arthropodborne encephalitis in the United States; however, there were sporadic cases among humans and outbreaks among horses.

In the western states, reports of equine encephalitis in the Columbia River Basin, including portions of Washington and Oregon, decreased after a peak was reached in late July and early August. Western Encephalitis virus (WE) was confirmed as the etiologic agent in 20 cases in Washington and in 34 cases in Oregon. From Idaho, 50 cases of equine encephalitis were reported, with many showing titer rise to WE virus. Four cases of equine encephalitis due to WE virus were reported from California, seven from New Mexico, and one from Texas. One case of

human encephalitis due to St. Louis Encephalitis virus (SLE) with onset in early August was reported from Nevada. In California, SLE virus was isolated from mosquito collections, but no human cases were reported.

In the midwestern states, four cases of human encephalitis due to California Encephalitis virus were confirmed (Continued on page 326)

in Ohio, six in Wisconsin, and one in Minnesota. Sera from other cases are undergoing laboratory study The pattern of cases has been consistent with that of recent years, with most cases occurring sporadically in young persons residing in these endemic areas.

In the eastern states, two cases of equine encephalitis due to Eastern Encephalitis virus (EE) were confirmed in South Carolina, two in North Carolina, and four in New Jersey. Since the earlier reports of human cases in Florida and equine cases in Georgia, no new EE virus activity has been reported from these two states (MMWR, Vol. 18, No. 31).
(Reported by Phillip K. Condit, M.D., Chief, Bureau of Communicable Diseases, California State Department of Public Health; E. Charlton Prather, M.D., Director, Division of Epidemiology, and Nathan J. Schneider, Ph.D., Chief, Bureau of Laboratories, Florida State Board of Health; John E. ## EPIDEMIOLOGIC NOTES AND REPORTS LEPTOSPIROSIS - Atlanta, Georgia

On August 29, 1969, a 41-year-old man with a history of alcoholism became ill with severe headache, muscle aches and cramps, shaking chills, fever, night sweats, pharyngitis, and migratory polyarthralgias. On September 2, he was admitted to a hospital, and the initial impression was influenza and early Laennec's cirrhosis. Subsequent hospital findings of aseptic meningitis, transient hyperbilirubinemia, and azotemia suggested the diagnosis of leptospirosis. On September 4, his serum had a titer of 1:400 to Leptospira icterohaemorrhagiae, and on September 12, a second serum specimen had a titer of greater than $1: 6,400$. The patient gave no history of recent exposure to animals. He did state that 18 days prior to on-
set of illness he crossed a leveled housing area where he first fell, receiving numerous lacerations and abrasions, and then stepped waist-deep into a pool of stagnant water.

On September 5, the man's family was also serologically tested; all had no detectable antibody to $L$. icterohaemorrhagiae.

The patient recovered during 2 weeks of hospitalization. No antibiotics were given since improvement was noted prior to the diagnosis of leptospirosis.
(Reported by John E. McCroan, Ph.D., Director, Epidemiologic Investigations Branch, Georgia Department of Public Health; and the Bacterial Diseases Branch, Epidemiology Program, NCDC; and an EIS Officer.)

## FATAL FALCIPARUM MALARIA - Tennessee

During the flight home from Vietnam on May 28, 1969, a 20 -year-old serviceman developed fever and chills followed by dry cough, nausea, vomiting, and mild diarrhea. Four days later, he visited his family physician who elicited a history of a dog bite 5 weeks earlier, for which the patient had already received 14 daily doses of duck embryo rabies vaccine. Because the present symptoms were consistent with an upper respiratory infection, he was given penicillin and told to return if he did not improve.

He continued to feel ill, but was not seen by the
physician until June 8, when his family found him semicomatose on the bathroom floor and brought him to the hospital. The admission temperature was $105^{\circ} \mathrm{F}$., and there was meningismus and right upper quadrant tenderness. The admission peripheral blood smear contained numerous Plasmodium falciparum ring forms. The hematocrit was 25 percent, white cell count $25,000 / \mathrm{mm}^{3}$, bilirubin 8.2 mg percent, BUN 78 mg percent, blood pH 7.10 , sodium 134 meq/ $/ 1$, potassium 6.0 meq $/ 1$, chloride $95 \mathrm{meq} / 1$, and $\mathrm{CO}_{2}$ $18.4 \mathrm{meq} / 1$. The cerebrospinal fluid pressure and protein
were elevated. Following consultation with an Army hospital, the patient was started on parenteral chloroquine and sulfisoxazole, but he steadily deteriorated.

Arrangements were made to air-evacuate the patient from Chattanooga to Walter Reed Army Hospital on June 10. Enroute, the flight surgeon controlled an episode of ventricular tachycardia with intravenous $\mathrm{CaCl}_{2}$. On arrival, the hematocrit was 12.5 percent, white cell count 50,000 , $\mathrm{mm}^{3}$, bilirubin 5.0 mg percent, BUN 236 mg percent, and the creatinine 4.0 mg percent. The prothrombin time was 40.5 seconds, and further evaluation revealed severe depression of clotting factors $I l, V, V I I, I X$, and $X$. The parasite count was in excess of $400,000 / \mathrm{mm}^{3}$ of blood. Carefully monitored intravenous quinine, hemodialysis, steroids, and fresh frozen plasma were followed by a decrease in parasite count to under $1,000 / \mathrm{mm}^{3}$ and correction of the metabolic disturbances. During the early hours of June 14, however, acute pulmonary edema developed; there was no response to therapy, and the patient died.

The autopsy showed bronchopneumonia, intra-alveolar
hemorrhage, hemoglobin pigment and casts, as well as tubular necrosis in the kidney, and diffuse petechial brain hemorrhages. Although no parasitized red blood cells could be identified in the capillaries, malaria pigment was present throughout the body.
(Reported by John C. Ellis, M.D., Tri-County Hospital, Ft. Oglethorpe, Georgia; Cecil B. Tucker, M.D., Director, Bureau of Preventive Health Services, Tennessee Department of Public Health; Edmund C. Tramont, Captain, MC, Walter Reed Army Hospital; and William E. Long, M.D., Chief, Epidemiology Division, District of Columbia Department of Public Health.)

## Editorial Note:

Chloroquine and sulfisoxazole combination therapy is undergoing clinical trial in the management of Vietnam strains of falciparum malaria. In this instance, parenteral quinine was not immediately available and might have been extremely hazardous in an oliguric patient when the facilities for determining serum quinine levels and performing renal dialysis were not available.

## OUTBREAK OF TUBERCULOSIS - Fargo, North Dakota

On November 25, 1968, active far-advanced bilateral cavitary tuberculosis was diagnosed in a 24 -year-old office worker (Case 1, Table 1) of a state health insurance company in Fargo, North Dakota. She had been ill for some time, but had continued working.

On December 3, following the diagnosis of this case, 224 of her fellow office workers were tuberculin tested by the Mantoux method with intermediate strength PPD. Fortytwo had a reaction of 10 mm or more, eight had reactions of 5 to 9 mm , and 13 were previously known reactors; except for these 13 known reactors, none gave a history of previous tuberculin testing. Between December 5 and 20, all 63 had a chest roentgenogram taken. One new active case of moderately advanced tuberculosis (Case 2) was diagnosed and 39 of the new reactors were placed on isoniazid (INH) prophylaxis during February and March.

In March, 185 employees, consisting of persons who had negative or doubtful reactions when tested in December and new employees, were tuberculin tested; 10 had reactions of 10 mm or greater and in five the reaction was 5 to 9 mm . Eight of the positive reactors and two individuals whose reactions were in the doubtful range were placed on INH.

In March and April, a second roentgenogram was taken on persons who were positive when tuberculin tested in December; four additional cases of tuberculosis were diagnosed (Cases 3,4,5, and 6). Two of these persons had been receiving INH for approximately 30 days. A review of the initial chest roentgenograms showed no evidence of active tuberculosis. On July 25, another case was diagnosed in another office worker (Case 7). This woman had

been started on INH in February but had received the drug for only a short period at her physician's recommendation. As a result of this case, employees were again tuberculin tested on July 29. No new cases were detected.

There was one other cas (Case 8) associated with this outbreak in a woman who did not work with the index case but who had contact with her at a kitchen ware party. This woman sought attention from her private physician after hearing about the index case.

The household contacts of all eight cases were also examined; no additional cases were found.
(Reported by James R. Amos, M.D., State Health Officer, and Kenneth Mosser, Director, Division of Communicable Disease, North Dakota State Department of Health; and D. H. Lawrence, M.D., Health Officer, Fargo City Health Department; and the Tuberculosis Branch, State and Community Services Division, NCDC.)

## FOLLOW-UP HUMAN RABIES - San Diego County, California

The 3 -year-old boy from Lakeside, San Diego County, California, who was bitten by a rabid bobcat on April 1, 1969, and who had onset of symptoms on April 18 followed on April 27 by coma, died on August 29 (MMWR, Vol. 18, Nos. 18 and 23). Nervous tissue obtained on May 9 was positive for rabies by fluorescent antibody staining. Results of a postmortem examination and cultures of materials obtained at that time are pending.
(Reported by J. B. Askew, M.D., Health Director, and Donald Ramras, M.D., Assistant Health Director, San Diego County Health Department; Richard Emmons, M.D., Public

Health Medical Officer, and James Chin, Head, Epidemiology, Bureau of Communicable Diseases, California State Department of Public Health; Samuel Giammona, M.D., Professor of Pediatrics, and William Nyhan, M.D., Professor and Chief of the Department of Pediatrics, University Hospital of San Diego County.)

## Editorial Note:

The death of this child 133 days after the onset of symptoms makes him the longest known American survivor of rabies.

## SURVEILLANCE SUMMARY

SALMONELLOSIS - April, May, and June 1969

During April, May, and June 1969, the total numbers of salmonella isolations from humans were $1,604,1,455$, and 1.721, respectively, and the weekly averages for the 3 months were 321, 364, and 430, respectively (Figure 1). For the same months 837,699 , and 620 nonhuman isolations were reported (Table 2).

Since the beginning of the Salmonella Surveillance Program at NCDC, a number of gradual changes in the frequencies of isolation of individual serotypes from humans have occurred. Although the 1968 total number of isolations of salmonellae increased by 5.8 percent from the 1963 total, the frequencies of isolation of S. enteritidis, S. thompson, and S. saint-paul doubled (Figure 2). In general, these
increases have been reported from all areas of the United States. No explanation for this phenomenon is apparent. (Reported by the Salmonellosis Unit, Enteric Diseases Section, Bacterial Diseases Branch, Epidemiology Program, $N C D C$.

## CURRENT TRENDS

MEASLES - United States and Puerta Rico

For the first 48 weeks of the Measles Epidemiologic Year 1968-69*, 22,875 cases of measles were reported to the NCDC. This is a 4.2 percent decrease in reported cases from the total for the comparable period during the epidemiologic year 1967-68 (Figure 3).

During the first 36 weeks of 1969 , there were 20,258 cases of measles reported (Table 3). This represents a 4 percent increase over the total for the same period last year. Although several areas showed sporadic increases over individual 4 -week periods, the overall increase was due to excess cases in three of the nine geographic divisions of the United States. The Middle Atlantic states showed a 115 percent increase in reported cases; approximately 80 percent of this was from New York City. The West North Central states had an excess of 181 cases or

37 percent over the preceding period, mostly from the state of Iowa. The South Atlantic states reported an excess of 992 cases or a 70 percent increase. This was predominantly due to marked increases in Delaware and Virginia. Puerto Rico showed a threefold increase in the same time period.

Although some of this increase may represent more efficient surveillance, it appears that the trend towards measles control, which began in 1963 with the advent of live vaccine, has been temporarily lessened and that, at least in some areas, a resurgence of measles may be at hand.
(Reported by the Field Services Branch, and Statistical Services Activity, Epidemiology Program, NCDC.)
*The Measles Epidemiologic Year begins with calendar week 41 and ends with week 40 of the following year.
