## EPIDEMIOLOGIC NOTES AND REPORTS BUBONIC PLAGUE - California

California's second case of bubonic plague this year (also its second case since 1965) was reported from Plumas County in a 45 -year-old lumberman. His symptoms began suddenly on July 7 and included high fever, shaking chills, severe myalgia, malaise, irritability, and painful right femoral adenopathy. Cultures of node aspirate were positive for Yersinia (Pasteurella) pestis. The patient was hospitalized on July 9 and is recovering on tetracycline therapy.

As in the previous case (MMWR, Vol. 19, No. 23), the illness was probably contracted in the northeast sector of California within a 50 mile radius of Mount Lassen. This patient also had visited Burney Falls State Park (Shasta County) but had other possible exposure while camping in Siskiyou and at his home in a wooded area of Plumas County. Investigation is in progress to define a focus (foci) of rodent plague in these areas.

## TICK PARALYSIS - Youngstown, Ohio

On the morning of May 17, 1970. when she awoke, a :3-year-old girl in loungstown, Ohio, felt dizzy and was unable to sit or stand. Within 5 hours she was brought to the emergency room of a hospital and was examined by a neurologist. She was found to have nystagmus, mild generalized weakness, and an injected left tympanic membrane. Deep tendon reflexes were intact. The initial impression was labyrinthitis. The admission BUN, blood sugar, complete blood count, and urinalysis were normal.

About $6 \quad 1 / 2$ hours after admission, her condition deteriorated rapidly. Although her vital signs remained normal, she developed symmetrical ascending flaccid paralysis.|She could no longer move her arms and legs, although weak movements of the hands and feet remained. Movements of the head were intact, but there was marked weakness of facial and masticator muscles. There was no intercostal paralysis; her cough was weak. She was unable to sit unsupported, and deep tendon and abdominal reflexes were absent. A spotty macular rash was present on the face and buttocks. Lumbar puncture revealed clear fluid under normal pressure, with no cells, protein 42 mg percent, sugar 47 mg percent, negative smear, and culture.

About 8 hours after admission, a large gravid tick was discovered in her scalp and was promptly removed by application of heat and the use of forceps. The girl subsequently made a rapid recovery; 18 hours after admission, she was
still weak, but could move all extremities well. Deep tendon reflexes had returned, she swallowed adequately, and eye movements were well coordinated. At 49 hours, she had completely recovered, was walking about, and had no evidence of weakness.

A history of prolonged play in a wild open field on the day before admission was obtained.
(Reported by Kurt J. Wegner, M.D., Director of Pediatrics, St. Elizabeth Hospital, Youngstown; Walter Greissinger, M.D., Health Commissioner, Youngstown Department of Health; John H. Ackerman, M.D., Chief, Bureau of Preventive Medicine, Ohio Department of Health.)

## Editorial Comment:

Tick-bite paralysis is an optionally reported disease to the CDC. From 1960 to 1968 , it was reported by two states: Oregon, 1 case each in 1966,1967 , and 1968 and Washington, 1 case in 1968 . It is known to occur uncommonly, but worldwide, affecting both man and animals, giving rise to a flaccid ascending major paralysis. The patient usually recovers promptly when the tick is removed. In northwestern United States, the tick, Dermacentor andersoni, is most frequently involved; other ticks are involved in the East and South, mainly in spring and early summer (1). Reference

## measles outbreaks - Oregon

Two outbreaks of measles were recently reported from Oregon. One occurred in Medford (Jackson County) and the other in the area of Salem (Marion and Polk Counties).
Medford Outbreak: The outbreak in Medford with eight cases occurred in late April 1970. Only one case had occurred in this area since May 1969. The index patient was an 8 -yearold second grader who had been in Oakland, California, 2 weeks prior to the onset of his illness. The second patient was a close school playmate and classmate and the third attended several classes with the index patient. The other five cases were in siblings of patients 2 and 3 . Six of the patients attended Jefferson School, the seventh attended Washington School, and one was a preschooler.

With the occurrence of cases 2 and 3 , school health cards for pupils at Jefferson School and another school were reviewed for a history of measles or measles immunization and revealed immunization levels of 45 and 42 percent, respectively. An immunization program was then held at Jefferson School, other Medford schools, and other County schools. A total of 3,289 school children and 377 preschoolers were given measles vaccine at the school clinics, and 293 vaccinations were given at the health department during this period. This raised the immunization level at Jefferson School to 88 percent and for the community to 85 percent.
Salem Outbreak: The outbreak in Salem with 43 cases began in May. These were the first cases in the area in more than a year. These cases were reported from two foci -St .

Joseph's parochial elementary school attended by students from all over the area and Hayesville Elementary School in another area of the city. At St. Joseph's the original cases were in five children in five different classrooms; all five had onset in the first week of May. The first case at Hayesville occurred in a fourth grade boy who had no contact with patients at St. Joseph's. At this school, cases were all contacts of the fourth grade index patient and were in 12 different classrooms. None of the patients at either school had been outside the area in the $3-4$ weeks prior to illness.

The Salem schools were to close for the summer within a week of the time the investigation was begun, but many of the children would be involved in harvesting strawberries immediately after close of school. Consequently, a school based immunized program was held between May 22 and 28 which involved 48 schools. A total of 1,719 school children and 541 preschoolers were immunized. Since this program, several cases have been reported in unimmunized children. Surveillance and investigation of all cases is continuing.
(Reported by Monroe Holmes, D.V.M., Public Health Veterinarian, Epidemiology Section, Oregon State Board of Health; Erin Merkel, M.D., Health Officer, and Robert Atwood, M.D., Assistant Health Officer, Jackson County; Elizabeth Love, Supervisor, Medford District School Nurses; Peter Batten, M.D., Health Officet, and John Chu, M.D., Marion County Health Department; E. B. Bossatti, M.D., Health Officer, Polk County; and an EIS Officer.)

# INTERNATIONAL NOTES 

SMALLPOX - Worldwide

From Jan. 1 through June 23, 1970, 16,604 cases of smallpox were reported to the Horld Health Organization (1). This represents a decrease of 10.6 percent from the 18,574 cases reported to the organization at this same time last year. The improvement during the past 12 months in reporting and surveillance programs, particularly in Afghanistan, Indonesia, most countries in Africa, and some of the states in Brazil. has tended to minimize the apparent effect of the worldwide eradication programs. Based on a composite analysis of smallpox trends in the separate countries during recent months. the WHO has estimated the eventual number of cases during 1970 to be no more than 35,000 to 40.000 cases. This will represent a decline of 25 to 35 percent of the number recorded during 1969. Smallpox ineidence rates per 100,000 population for the regions in the world which were endemic in 1965 are presented in Figure 1. A downward trend was observed in all of the four endemic areas. with the most dramatic decline in West and Central Africa.

The number of countries recording at least one case of smallpox has also declined. During 1967 a total of 43 countries recorded at least one case; in 1968 this number Was reduced to 38 countries, and in 1969 a further reduction to 29 countries was observed. During 197018 countries have reported smallpox. In four of these, Federal Republic of Germany, Saudi Arabia. Uganda, and Zambia, cases of smallpox could be attributed entirely to importations from endemic areas.

## West and Central Africa

After 3 years of an intensive eradication program, this region of 20 countries has almost entirely interrupted the transmission of smallpox. The program to date has given approximately $114.000,000$ vaccinations. To date in 1970 only one country, Nigeria, has reported any smallpox. The Outhreak in Nigeria has been traced back to December 1969 and in believed to be directly related to a known outbreak in early 1969 (MMWR, Vol. 19, No. 22).

## East and South Africa

During 1969 reported cases of smallpox in this area declined by 42 percent from the total in 1968. In 1970 smallpox cases have appeared in nine countries (Uganda and $Z_{\text {ambia having experienced importations) and appears to be }}$ confined to three geographic areas in East and South frica: (1) Democratic Republic of Congo-Rwanda-Burundi; (2) Ethiopia-Sudan; and (3) South Africa. Intensive smallpox vaccination programs are being carried out in all areas with the exception of South Africa for which little information is atailable regarding the extent of smallpox control activities. South America

Since 1967 all reported smallpox cases in this area have occurred in Brazil or as a result of importation from Brazil. The smallpox eradication program began in 1967 in $\mathrm{Brazil}^{\text {to }}$. the only endemic country in the Americas. Approxi${ }^{\text {to }}$ ately 62.000 .000 vaccinations have been given with

campaigns completed in 14 of the 27 states and in progress in five other states (2).

Smallpox incidence increased very sharply during 1969 in Brazil with a total of 7,391 cases reported, the highest incidence since 1962. This increase in cases began in July 1969 and coincided with the development of a more efficient surveillance program. For example, in one state an average of 40 cases was discovered as a result of epidemic investigations for each case reported.

## Asia

Smallpox incidence in Asia has shown a steady and continuous decline since the beginning of the eradication program. This decline is primarily accounted for by the decrease in reported cases in India. In other Asian countries (Afghanistan, Indonesia, Nepal, and Pakistan), eradication programs have been initiated during the past 2 years and have been steadily intensified. Each of these programs has substantially increased their surveillance network, and field investigations have found that for each reported case an additional 2 to 10 cases have occurred.
